Abstract

Background: Both smoked and smokeless tobacco use have deleterious effects on most major organ systems including the reproductive system. We conducted a systematic review on smokeless tobacco (SLT) use and reproductive outcomes among women.

Methods: We searched Pubmed, ProQuest, Cochrane, Wiley and Emerald databases for studies involving smokeless tobacco use in women with any or a combination of three conditions: infertility, menstrual disorders and pelvic inflammatory disease (PID). Eligibility criteria included English language publications from 1st January 1990 - 31st October 2020. CADIMA software used for filtering the studies and modified SIGN checklist for the quality assessment. The findings are reported as per the PRISMA guidelines. The AXIS and ROBIN E tool were used for assessment of risk of bias.

Results: In total, three studies addressed our research question. Two studies addressed infertility (prospective cohort: n=501, cross sectional: n=192) of which, the cross-sectional study compared the mean cotinine levels between those with infertility, menstrual disorders and PID. This study also explored the association between SLT and PID. PID was the most common gynecological complaint. Women with PID had significantly higher urinary cotinine levels = 24.95±12.259) ng/ml (p=0.0144). Mean urinary cotinine in women with menstrual complaints was 19.32±10.29 ng/ml.

Any reports and responses or comments on the article can be found at the end of the article.
The other study used population-based sampling of 501 couples who attempted pregnancy (enrolled in the LIFE Study). Results showed that 9% and 2% (n=28) of men used snuff and chewed tobacco respectively, and few of the women used smokeless tobacco. Time to pregnancy was shorter among smokeless tobacco users relative to smokers.

**Conclusions:** Available studies exploring associations between SLT and reproductive outcomes are inconclusive due to limitations in the study methodologies. More studies with robust study designs are required from low- and middle-income countries with high prevalence of SLT use.

**Keywords**
Smokeless Tobacco, infertility, menstruation, abnormal uterine bleeding, pelvic infections, reproductive health, women
Introduction

Use of both smoked and smokeless forms of tobacco is a major cause of preventable morbidity and mortality. It kills half of all its lifetime users (WHO, 2011) and more than 8 million people each year, out of which, 1.2 million die due to second hand smoke (WHO, 2019). Toxic and carcinogenic chemicals in tobacco along with other ingredients that are added to them are known to be causally associated with several non-communicable diseases (NCDs) including cancer, especially oral cancer which is the leading cancer among men and the third most common cancer among women in India (Bhisey, 2012).

Smokeless tobacco (SLT) is “consumed without combustion at the time of use” (WHO, 2015). It is generally used orally (sucked, chewed, dipped or held in the mouth, used as dentifrice or toothpaste) or nasally resulting in nicotine absorption across the mucous membrane, along with other chemicals. Majority of SLT users, approximately 286 million people, live in low and middle-income countries in South-East Asia region. Three countries, namely India, Bangladesh, and Myanmar, host around 86% of the global users (NCI &CDC, 2014). As per Global Adult Tobacco survey 2016-17, women accounted for 2% among around 99.5 million adults current smokers. In contrast, 12.8% of women used SLT out of 199.4 million adults (GATS, 2017).

SLT use is addictive; it leads to oral health problems and plays a contributory role in the development of cardiovascular disorders, fatal ischemic heart disease, stroke, peripheral vascular diseases, peptic ulcers, type 2 diabetes, chronic rhinitis, foetal morbidity and mortality (WHO, 2015; Inamdar et al., 2015; Suliankatchi and Sinha, 2016; Hosssain et al., 2017). The leading health consequences related to SLT use in Southeast Asia include cancers of numerous sites along with poor reproductive outcomes (World Health Organization. News release 11th Sept 2013).

Tobacco use in India is majorly considered a male-dominant behavior. However, over the past decade, the use of SLT products by Indian women is substantial and increasing, with adverse consequences for oral (Niaz et al., 2017; Singh et al., 2020) and perinatal health (Inamdar et al., 2015; Suliankatchi and Sinha, 2016; Nair et al., 2015). Women who use SLT are at risk of oral (Singh et al., 2020) and pharyngeal cancers (Niaz et al., 2017; Datta et al., 2014; Sinha et al., 2016; Aw and Patil, 2016), esophageal cancer (Niaz et al., 2017; Datta et al., 2014; Sinha et al., 2016; Aw and Patil, 2016), cervical cancer, ischemic heart disease (IHD) (Sinha et al., 2015) and osteoporosis (Ayo-Yusuf and Olutola, 2014). Compounds in SLT products such as nicotine act as neuro-teratogens as they can cross the placental barrier (Liao et al., 2012) affecting the fetal development along with other pregnancy complications like pre-term delivery, low-birth weight (Inamdar et al., 2015; Suliankatchi and Sinha, 2016) increased stillbirth risk (Hossain et al., 2017) and risk of cancers in the developing fetus (Rogers et al., 2009). However, there is little evidence that explores the association between SLT use and reproductive health of women. Therefore, we planned to systematically conduct a review on the impact of smokeless tobacco (SLT) use and reproductive health outcomes among women, namely infertility, menstrual disorders and pelvic inflammatory disease.

Methods

The protocol was registered on PROSPERO on 2nd October 2020 (CRD42020207176). This paper is reported in line with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines (Radhika, 2021).
We did an extensive literature search that described the association between SLT use and selected reproductive outcomes in women. For this, we selected three common reproductive outcomes, namely infertility, menstrual disorders and pelvic inflammatory disease. The search terms revolved around P (population): women, E (exposure): exposure to SLT, C (control): women who were not exposed to SLT, O (outcome): reproductive outcomes in women that included infertility, menstrual disorders, and pelvic inflammatory disorder (PID). The reference period was from 01 January 1990 to 31st October 2020.

Eligibility criteria
Publications including reviews, original trials and conference proceedings documenting any form of SLT use along with the three selected reproductive outcomes in English language within the timeframe were considered for the inclusion.

Information sources
Studies were identified by searching electronic databases (Pubmed, Wiley, Cochrane Library, Emerald and ProQuest) in addition to scanning reference lists of articles using the chosen keywords for all three reproductive outcomes separately.

Search strategy
Search strings used for infertility among women and SLT were: (Smokeless OR Chew OR Chewing OR Dipping OR Snuff OR toothpaste OR dentifrice OR paan masala OR betel quid OR betel quid OR areca nut OR arecam nut) AND (Tobacco OR Tobaccos OR Gutka OR Gutkas OR Snuff OR Mint) AND (Female OR Women) AND (Infertility OR Subfertility OR Sub Fertility OR sterility OR infertility OR fertile).

Search strings used for Menstrual disorders and SLT were: (Smokeless OR Chew OR Chewing OR Dipping OR Snuff OR toothpaste OR dentifrice OR paan masala OR betel quid OR betel quid OR areca nut OR arecam nut) AND (Tobacco OR Tobaccos OR Gutka OR Gutkas OR Snuff OR Mint) AND (Female OR Women) AND (menstrual OR menstruation OR bleeding OR menorrhagia OR Hypermenorrhoea OR Hypermenorrhoea OR Hypomenorrhoea OR Hypomenorrhoea OR Dysmenorrhoea OR dysmenorrhoea OR Abnormal uterine bleeding OR amenorrhea OR menometrorrhagia OR metrorrhagia OR dysfunctional uterine bleeding.

For PID and SLT use, search strings used were (Smokeless OR Chew OR Chewing OR Dipping OR Snuff OR toothpaste OR dentifrice OR paan masala OR betel quid OR areca nut) AND (Tobacco OR Tobaccos OR Gutka OR Gutkas OR Snuff OR Mint) AND (Female OR Women) AND (infection OR inflammation OR pelvic inflammatory disease OR PID OR genital infections OR genital tuberculosis OR tubo-ovarian mass OR Salpingitis OR salpingo-oophoritis OR endometritis OR adenitis OR parametritis).

Study selection
We included studies irrespective of sample size. After duplicate removal by CADIMA, every record was screened by two reviewers independently using the title. Those accepted by both were subjected to abstract review. In case of any disagreement, arbitration was done by a senior member from the team. For the selected abstracts, full articles were obtained, and quality check was performed by two reviewers independently using the modified SIGN checklist. Those selected at this stage were eligible for the review. The study selection is mentioned according to reproductive outcomes selected and reported according to PRISMA guidelines. The AXIS tool was used to assess risk of bias (Ma et al., 2020) for cross sectional study and the ROBIN E tool was used for prospective studies.

Data items and data collection process
Full text appraisal for study selection was done by two authors independently. Title & abstract filtering was done with CADIMA. Information was extracted from all the eligible studies on a predesigned format (Tables 2–4) including a range of study variables relating to the design, objectives, and outcomes. For each of the reproductive outcomes, studies included were summarized separately.

Results
Search for infertility among women and SLT use resulted in 1093 results which were run through CADIMA for removal of the duplicate studies, which gave a final of 1062 results (9 from Pubmed; 44 from Wiley; 6 from Emerald; 11 from Cochrane and 992 from ProQuest). That for Menstrual disorders and SLT gave 1330 results. These results were run through CADIMA for removal of the duplicate studies, which gave a final of 1294 results (44 from Pubmed; 19 from Wiley; 25 from Cochrane and 1206 from ProQuest). For PID and SLT use, there were 3929 results. These results were run through CADIMA for removal of the duplicate studies, which gave a final of 3808 results (205 from pubmed; 27 from wiley; 46 from Cochrane and 3530 from proquest) (Table 1).
The search revealed a total of two studies (prospective cohort, n = 501 and cross sectional, n = 192) addressing our research question related to infertility (Figure 1, Table 2).

The prospective cohort study used population-based sampling with 501 couples who attempted pregnancy in Michigan and Texas, 2005–2009 (enrolled in the LIFE Study). Results showed that only 9% and 2% (n = 28) of men used snuff and smokeless tobacco respectively and very few women used smokeless tobacco. Smokers showed higher cadmium levels than SLT, adjusted for cadmium attenuated the cigarette–time-to-pregnancy (TTP) association, especially among

</tr>
<tr>
<td><strong>Primary outcome</strong></td>
<td>11% of females and 15% of males smoked cigarettes. Among men, 14% smoked cigars, 9% used snuff, and 2% used chew. Very few women used smokeless tobacco. Cadmium levels were higher in smokers than smokeless tobacco and never users; adjusting for cadmium attenuated the cigarette–TTP association, particularly among women. TTP was shorter among smokeless tobacco users relative to smokers (FOR: 2.86, 95% CI: 1.47, 5.57).</td>
<td></td>
</tr>
</tbody>
</table>
women. Shorter TTP was observed among SLT users in comparison to smokers (FOR [fecundability odds ratio]: 2.86, 95% confidence interval [CI]: 1.47, 5.57). Compared with never users of tobacco, smoking by females (FOR: 0.53, 95% CI: 0.33, 0.85) was individually associated with longer TTP; for males, smoking remained significant (FOR: 0.46, 95% CI: 0.27, 0.79) when modeling partners together (Sapra et al., 2016).

A cross sectional study carried out in India to evaluate the urinary cotinine levels in three common categories of gynecological complaints, among 192 women of reproductive age residing in East Delhi who sought treatment from a Government Medical college. Results showed that urinary cotinine levels in women not exposed to SHS ranged widely from 8.09 to 63.44 ng/ml with a mean at 23.60±12.00 ng/ml. PID was the most common gynecological complaint. Mean urinary cotinine levels in infertile women were 22.42±12.72 ng/ml. The limitations of this study were that the sample size was not enough, other confounding variables were not considered and none of the participants admitted to smoking or use of SLT though an earlier published study by the same authors identified about 8.4% women were using locally made tobacco containing toothpaste for discomfort in teeth and gums (Radhika et al., 2014, 2017).

The same study found that mean urinary cotinine levels in women with menstrual complaints was $19.32 \pm 10.29$ ng/ml. Out of 1330 articles obtained on initial search, this was the only study selected in our review to study the association between SLT and menstrual problems (Figure 2, Table 3). For the question related to PID, another study (Simen-Kapeu et al., 2009) in addition to this study was selected (Figure 3, Table 4). Women with PID had significantly higher urinary cotinine levels = $24.95 \pm 12.259$ ng/ml ($p = 0.0144$) (Radhika et al., 2017).

Another study (Simen-Kapeu et al., 2009) compared the association between tobacco use (smoking and chewing) and the risk of multiple human papillomavirus (HPV) infections and cervical squamous intraepithelial lesions (SILs) in two populations with different exposure. For this, baseline data from 2144 women from Côte d’Ivoire, West Africa and 415 women from Finland, Northern Europe regarding cervical screening, HPV positivity and tobacco use (smoking and chewing habits) was re-analyzed to determine the association between tobacco chewing in Côte d’Ivoire and tobacco smoking in Finland and the age stratified risk of multiple HPV infections and cervical SIL. Results show that in Côte d’Ivoire tobacco chewing (2.6%) was more common than tobacco smoking (1.4%). In 236 cases (eligible women with SIL), mean age of the women was 28.4 ± 6.6 years with low-grade SIL in 165 and high-grade SIL in 71. Tobacco users (smokers and chewers) showed an increased risk of LSIL. Tobacco chewers were at 5 times higher risk for HSIL in both younger age group (<30 years) with OR: 5.5, 95% CI: 1.2-26 and older age group (≥30 years of age) with OR: 5.5, 95% CI: 2.1-14) in comparison to non-chewers. Age-adjusted OR of cervical HSIL was significantly higher among tobacco chewers. Increased risk of LSIL and HSIL (not significant) was found in HPV positive women ≥ 30 years of age who were actively exposed to tobacco through smoking or chewing was seen.

Having multiple HPV infections was common in HPV16 and/or HPV18 infected women (60.4% in Finland and 47.2% in Côte d’Ivoire). There was no increased risk of multiple HPV infections among tobacco consumers. It was found that

women ≥ 30 years of age exposed to tobacco through smoking in Finland (OR: 2.2, 95% CI: 0.5-8.7) and chewing in Côte d’Ivoire (OR: 5.5, 95% CI: 2.1-14) had a moderately or highly increased risk of high-grade SIL, respectively. In the latter, the risk was statistically significant. Sampling bias was seen in the study as very few Ivorian women reported smoking evaluation, for this habit alone, and the regression analysis was restricted to Finnish women (Simen-Kapeu et al., 2009).

The risk of bias assessed using appraisal tool for cross sectional studies (AXIS) for one and ROBIN E for observational studies. Risk of bias for cross sectional study was high due to the small sample size but the those for the prospective studies was low.
Discussion

There is a high prevalence of SLT use in low- and middle-income countries. India, Bangladesh, Egypt, Nigeria and Philippines have a high burden of SLT use though India carries 83% of global burden. There are nearly 58.2 million women (12.8% aged more than 15 years) consuming some form of SLT in India (GATS 2 survey 2016-17). Adverse effects of SLT use among women include oro-pharyngeal cancers, ischemic heart disease and osteoporosis (Sinha et al., 2018; Spangler et al., 2001). It is associated with infertility and poor pregnancy outcomes. Nicotine crosses the placental barrier resulting in a neuroteratogenic effect in the developing fetus. A limited number of studies investigated the relationship between SLT use among women and pelvic infections and menstrual function.

This systematically conducted rapid review to study association between SLT use and reproductive health of women yielded a total of three studies with findings from four different countries, namely India, USA, Finland and Cote d'Ivoire and Finland. The differences in the study methodologies precluded us from combining the study findings.

Infertility was measured in terms of TTP and Urinary cotinine levels and both were seen to be higher in SLT users. Women with PID had highest mean urinary cotinine levels among the three, followed by infertility and menstrual complaints respectively (Radhika et al., 2017). Another study showed longer TTP for cotinine levels more than 10ng/ml for SLT users (Sapra et al., 2016). Another study comparing association between tobacco smoking and chewing with risk of PID in two populations with different exposures showed that SLT users were at a five times higher risk of SIL in comparison to non-chewers irrespective of age (Simen-Kapeu et al., 2009). Results were however inconclusive regarding strong associations between SLT use and reproductive health in women.

Biologic fertility can be assessed using TTP. A study based in a community setting showed a remarkably comprehensible association between female smoking and sub-fecundity during the most recent waiting TTP (Kassa and Kebede, 2018). However, similar studies addressing the effects of SLT were not available. TTP was seen to be lesser in SLT users than smokers, however this aspect needs more research with comparisons drawn with smokers and tobacco nonusers.

Cigarette smoking was also seen to be associated with an adverse effect on ovarian function and hence on fertility among women. Evidence suggests that there is an association between cigarette smoking and reduced fertility (risk of delayed conception), even at low doses (Hatch et al., 2012; Gormack et al., 2015). Since the active metabolite is similar, it is natural to expect some effects on the reproductive outcomes i.e. menstrual function, infertility, PID and pregnancy outcomes with SLT use also. However, there is a dearth of good quality studies to ascertain such an association.

Nicotine levels are found to be highest in bidis, followed by chewed tobacco and cigarettes (Amith et al., 2018). Nevertheless, SLT products are more often abused than smoked tobacco products ( Sharma et al., 2015) and serum nicotine levels remain in significant amounts for a longer time period (Mala et al., 2016). Like smoked form, SLT use causes alteration of the immune response to infections and has a damaging effect on majority of organ systems in the body including the reproductive system (Willis et al., 2012). This justifies the biological plausibility between SLT and reproductive outcomes.

To conclude, the number of studies addressing the association between SLT use and reproductive health of women were very few despite the high prevalence of use in the South East Asia region. Impact of SLT on reproductive health of women requires more research. In this rapid review, we followed the principles of systematic review that offers strength to the study. We have considered the major reproductive outcomes comprehensively. However, we restricted our search to English papers that poses a limitation. In addition, our reference period was from 1990, though it possibly would not have made a difference even if we went beyond that timeline. Though our results show that there might be an association between the SLT and poor reproductive outcomes, we recommend more studies on this topic with robust study designs for conclusive results.

In our review, we identified gaps in knowledge concerning the association of SLT use with reproductive outcomes in women. Research is needed to determine the impact of smoked and smokeless tobacco products on women’s reproductive health.

I have read the author’s comments as well as the revised version of the article uploaded on the website. The fundamental issues raised in my first review have not yet been addressed. Hence, I’m of the opinion that the systematic review does not fulfil its desired objectives and should not be published in its present form.

Competing Interests: No competing interests were disclosed.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to state that I do not consider it to be of an acceptable scientific standard, for reasons outlined above.

The authors use the term reproductive outcomes in the title and then use the terms “reproductive outcomes” and “reproductive health” interchangeably throughout the review. It may be beneficial to use standardized definitions in the review. Rationale also needs to be provided why these 3 particular outcomes namely infertility, menstrual disorders, and pelvic inflammatory disease have been the focus of the review rather than the more commonly reported reproductive outcomes low birth weight, stillbirth, spontaneous abortion, preterm birth and so on in studies related to smokeless tobacco.

In two of the studies, included in the review, the women participants were not consuming smokeless tobacco which is the focus of the review. So the authors need to clarify whether these studies fulfilled their inclusion and exclusion criteria.

All the above points have a bearing on the conclusions drawn from the review and hence need to be addressed.

The discussion also focuses more on smoking rather than smokeless tobacco.

**Are the rationale for, and objectives of, the Systematic Review clearly stated?**
Partly

**Are sufficient details of the methods and analysis provided to allow replication by others?**
Partly

**Is the statistical analysis and its interpretation appropriate?**
Partly

**Are the conclusions drawn adequately supported by the results presented in the review?**
Partly

Uttar Pradesh, India

The objective of the systematic review, as stated by the authors, is to review the association of SLT use and reproductive health among women. The methodology, search strings, eligibility criteria are all suitable to the objective. However, I have major concerns about the results.

1. What were the exclusion criteria? If the E in PECO is an exposure to SLT, then studies reporting on smoking or secondhand smoke should be excluded from the review.

2. Of the three studies that the authors claim to have 'addressed' their research question, the study from India addresses secondhand smoke. Neither of the participants admitted to smoking or SLT use. Hence, this study does not fulfill the eligibility criteria. In the report from Michigan and Texas, none of the female participants used SLT while only a small fraction of males consumed SLT in the form of snuff or chewing products. A close review of their results shows that impact of SLT on infertility is compared to smokers but not to never-users (could have been insignificant due to the low numbers of SLT users). Hence, this study also, in my opinion is not worth being included in the review.

That leaves only one study from Cote d'Ivoire, West Africa and Finland, Northern Europe that evaluated the risk of HPV and SIL in tobacco users, including SLT users.

3. The discussion section also pertains to smoking rather than SLT which is the actual topic of the review.

4. When talking of reproductive outcomes, why did the authors not include pregnancy outcomes like prematurity, stillbirth, low birth weight etc.?

Are the rationale for, and objectives of, the Systematic Review clearly stated?
Yes

Are sufficient details of the methods and analysis provided to allow replication by others?
Yes

Is the statistical analysis and its interpretation appropriate?
No

Are the conclusions drawn adequately supported by the results presented in the review?
No

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Smokeless tobacco and health impact

I confirm that I have read this submission and believe that I have an appropriate level of expertise to state that I do not consider it to be of an acceptable scientific standard, for reasons outlined above.
1. What were the exclusion criteria? If the E in PECO is an exposure to SLT, then studies reporting on smoking or secondhand smoke should be excluded from the review.

Response: The query is well placed. Exposure to SLT is only qualified for inclusion.

2. Of the three studies that the authors claim to have 'addressed' their research question, the study from India addresses secondhand smoke. Neither of the participants admitted to smoking or SLT use. Hence, this study does not fulfill the eligibility criteria. In the report from Michigan and Texas, none of the female participants used SLT while only a small fraction of males consumed SLT in the form of snuff or chewing products. A close review of their results shows that impact of SLT on infertility is compared to smokers but not to never-users (could have been insignificant due to the low numbers of SLT users). Hence, this study also, in my opinion is not worth being included in the review.

Response: Thanks for this important observation.

1. The study from India found that even though none of the patients consented to use SLT, the urinary cotinine levels were quite high ("Urinary cotinine levels in women not exposed to SHS (162/192) ranged widely from 8.09 to 63.44 ng/ml with a mean of 23.60 * 12.00 ng/ml"). Following secondhand exposure to tobacco smoke, cotinine levels rarely exceed 10 ng/ml. In addition, patients’ histories of addictions can be very inconsistent and unreliable. Therefore, the study was included in the review.

2. There are few studies on SLT and infertility, and their sample sizes are small. Despite its small numbers, the result was included for review due to its importance

That leaves only one study from Cote d’Ivoire, West Africa and Finland, Northern Europe that evaluated the risk of HPV and SIL in tobacco users, including SLT users.

3. The discussion section also pertains to smoking rather than SLT which is the actual topic of the review.

Response: Thanks for the suggestion, it has now been revised.

4. When talking of reproductive outcomes, why did the authors not include pregnancy outcomes like prematurity, stillbirth, low birth weight etc.?
Response: Yes, this aspect was considered when planning the study. We planned that gynecological aspects can be emphasized in the present review. Pregnancy outcomes will be examined in another study.

Are the rationale for, and objectives of, the Systematic Review clearly stated?
Yes

Are sufficient details of the methods and analysis provided to allow replication by others?
Yes

Is the statistical analysis and its interpretation appropriate?
No
Response: We request to have better clarity please specially the specific point of concern.

Are the conclusions drawn adequately supported by the results presented in the review?
No
Response: It has been revised.

Reviewer 2

Are the rationale for, and objectives of, the Systematic Review clearly stated?
Partly
