Spectrum of Sellar and Parasellar Region Lesions: A retrospective study from Basrah, Iraq [version 1; referees: 1 approved, 1 approved with reservations]

Faiha Specialized Diabetes, Endocrine and Metabolism Center (FDEMC), Diabetes, Endocrine and Metabolism Division, Department of Medicine, Basrah College of Medicine, Hattin post office. P.O Box: 142, Basrah, 61013, Iraq

Abstract

Background: Sellar and parasellar region lesions spectrum includes a wide variety of diseases. This study aimed at providing a comprehensive overview of such lesions in patients from Faiha Specialized Diabetes, Endocrine and Metabolism Center (FDEMC) in Basrah (Southern Iraq).

Methods: Retrospective data analysis from FDEMC for the period January 2012 through June 2017. We included all patients with sellar and parasellar region lesions who received a MRI scan on their pituitary region

Results: The total enrolled patients were 232 (84 men and 148 women) with age range 15-75 years. Pituitary disease and adenoma were more common among women. Those with macroadenoma were older than those with microadenoma, with nearly equal gender prevalence of macroadenoma. Pituitary adenoma constituted the bulk of pituitary disease in this setting (67.2%). Growth hormone secreting adenoma were the most common adenoma seen in 41.0%, followed by clinically non-functioning pituitary adenoma (NFPA) in 31.4% and prolactinoma in 26.9%. About 64.8% of pituitary adenoma was macroadenoma. Macroadenoma was seen in 73.4% of growth hormone secreting adenoma (acromegaly), 61.2% in NFPA and 62.0% of prolactinoma (of them six were giant prolactinoma).

Conclusion: Pituitary adenoma constituted the bulk of sellar and parasellar region lesions, growth hormone secreting adenoma is the most common adenoma followed by NFPA and prolactinoma due to referral bias. A change in practice of adenoma treatment is needed.

Keywords
Sellar and parasellar region lesions, pituitary disease, pituitary adenoma, classification, epidemiology.

Introduction
Sellar and parasellar region lesions spectrum includes a wide variety of conditions ranging from adenoma to empty sella syndrome, apoplexy, congenital or acquired condition. Other than adenoma, genetic causes of pituitary disease are increasingly recognized.

Pituitary adenomas are not rare and account for 20% all intracranial tumors. Half of these secrete hormones, and half are microadenoma. Clinically non-functioning adenomas (NFPA) constitute 15–54% of all adenomas. Prolactinomas accounts for 32–66%, growth hormone secreting adenoma (acromegaly) account for 8–16%, adrenocorticotropic hormone (ACTH)-secreting adenoma (Cushing's disease) forms 2–6%, and TSHoma accounts for less than 1%. These pituitary adenomas behave as typical or have a more aggressive to malignant behavior. They can cause mass effect, in addition to hypersecretion or hypopituitarism.

Advances in neuroradiology have opened the door for earlier and easier diagnosis of pituitary disease and other sellar and suprasellar lesions.

The Faiha Specialized Diabetes, Endocrine, and Metabolism Center (FDEMC) in Basrah is a tertiary referral center receiving patients with pituitary diseases from most of Southern Iraq. The FDEMC is trying to adapt the three mission criteria of the pituitary center of excellence, which includes care and support for patients, fellowship training and contribution to pituitary disease research. To our knowledge, there are no studies on sellar and parasellar region lesions in Iraq.

This study aimed at providing a comprehensive overview of sellar and parasellar region lesions for patients from FDEMC in Basrah (Southern Iraq).

Methods
Study design
Retrospective data analysis of the FDEMC database for the period January 2012 through June 2017.

Inclusion criteria: We included all patients, age range 15–75 years with sellar and parasellar region lesions who have received a MRI scan on their pituitary region.

Exclusion criteria: patients with sellar and parasellar region lesions who did not receive a MRI scan.

Definition of variables
Sequences of pituitary MRI imaging were classified according to the international standard. Adenomas were classified as macroadenoma if these were 10 mm or more in size, while microadenoma if less than 10 mm and giant prolactinoma if these were 4 cm and above.

Pituitary adenoma, NFPA, prolactinoma, growth hormone secreting adenoma (acromegaly), and ACTH-secreting adenoma were defined according to the usual criteria.

Hypopituitarism, whether postoperative or in those with or without adenoma, was considered according to the hormonal assessment with basal and dynamic hormonal tests.

Empty sella syndrome, whether primary or secondary to surgery or apoplexy, were considered based on MRI findings.

Craniohypophysealoma diagnosis was based on clinical behavior with MRI and pathological diagnosis.

Data analysis
Analysis was done in July 2017. All patients with labeling diagnosis of pituitary disease were included. Data were included on an Excel spreadsheet and transferred to SPSS for Windows, Version 23.0 (SPSS Inc., Chicago, USA).

Continuous variables were summeried as number and percentage and dichotomous varibales as mean ±SD.

Ethics statement
The ethics committee of the Medical College in Basrah University approved the study design and the Center authorities agreed to review the patients data. At the time of registration in the Center, all patients included in this study approved the use of their clinical information for research purposes.

Results
A total of 232 patients were included in this study. Pituitary disease and adenoma were more common among women (Table 1). Those with macroadenoma were older than those with microadenoma with nearly equal gender prevalence of macroadenoma. Four patients died; two with growth hormone secreting adenoma (acromegaly) and advanced cardiovascular disease, and two with prolactinoma that caused hypopituitarism and adrenal failure.

Table 2 shows that pituitary adenoma constituted the bulk of pituitary disease in this registry (67.2%). Growth hormone secreting adenoma (acromegaly) were the commonest adenoma seen in 41.0% followed by NFPA in 31.4% than prolactinoma in 26.9%. Hypopituitarism due to various causes was observed in 24.5% in this series. Empty sella syndrome, whether primary or secondary, were seen in 9.4%. Craniohypophysealoma and Sheehan syndrome were seen in 3.9% each. Meningioma based on MRI finding was been observed in 4 patients (1.7%).

In this study, 64.8% of pituitary adenoma were macroadenomas (Table 3). Macroadenoma was seen in 73.4% of acromegaly, 61.2% in NFPA and 62.0% of prolactinoma (of them six were giant prolactinoma).

In Table 4 we see hypophysectomy whether transsphenoidal or transcranial or both was performed in 45 patients with pituitary adenoma (28.8%). Stereotactic radiosurgery is done in 5 patients (3.2%) with pituitary adenoma. Growth hormone secreting adenoma (acromegaly) and prolactinomas were treated primarily with medical therapy (71.4% and 76.1% respectively).

Discussion

All pituitary disease and adenoma were more common among women in this study. The gender predominance among patients with pituitary adenoma is variable in the literature depending on hormone secretion and age of the patients, the size of the tumor and female dominance is not clear. However, female dominance has been seen in Saudi Arabia and one series from Argentina. Those with macroadenoma tend to be older in age with no difference in the prevalence between men or women.

Dataset 1. Description of patients included in the study

http://dx.doi.org/10.5256/f1000research.13632.d197439
Seen in about two-thirds of patients, pituitary adenoma constituted the main bulk of pituitary disease in this study, which is compatible with reports in the literature.16

The commonest pituitary adenoma was growth hormone secreting adenoma (acromegaly), followed by NFPA and prolactinoma. This is entirely different from the literature on the prevalence of pituitary adenoma.16,17,19 This could be attributed to selection bias because only growth hormone secreting adenoma (acromegaly) patients are being referred, while NFPA and prolactinoma were treated by different specialties, such as neurosurgeons or gynecologists, without referral to a specialized Center like FDEMC. In Basrah, most cases of hyperprolactinemia were seen by a gynecologist because of amenorrhea and infertility, and the neurosurgeon follows patients with NFPA without referring them.

Hypopituitarism is prevalent in a quarter of this pituitary centre, from different causes, ranging from macroadenoma to hypophysectomy. Evaluation for hypopituitarism remains an integral part of the workup for any pituitary lesions because missing such diagnosis could be catastrophic.9,13 This figure is far higher than that of Saudi Arabia, which was 1.2%.17

Empty sella syndrome was seen in 9.4% of patients in this study, which can be primary or secondary to surgery or apoplexy. Empty sella syndrome needs an extensive workup to assess pituitary function.20

Craniopharyngioma and Sheehan syndrome are two diseases with a different spectrum of age distribution, but they were seen at the same frequency in this cohort. Craniopharyngioma is a disease of childhood and adolescence.21 Sheehan syndrome is supposed to be rare in developed countries, but is still seen in developing countries.22

Less than two thirds of adenoma in this study were macroadenomas. While in most series macroadenomas constitute 50% of the pituitary adenomas; however in Canada, a similar finding has been seen compared with this study.23 Again this could be explained by referral bias in this study. In Saudi Arabia, microadenomas were more prevalent.17

For growth hormone secreting adenoma (acromegaly), more than two thirds were macroadenomas, which is established fact for all acromegaly.22,23

NFPA was a macroadenoma and seen at around 60% in this study. A similar finding was seen in a previous series.2

Prolactinomas were macroadenoma in around 60% of cases in this study. This differs from the literature, where more than 90% of prolactinomas were microadenomas.2,18

Hypophysectomy-transsphenoidal as surgical treatment was done in one third of pituitary adenomas, while transcranial approach or stereotactic radiosurgery was contemplated in the minority. This is a typical approach for most of the pituitary adenomas.2,26 For growth hormone secreting adenoma (acromegaly), the primary treatment in this study was medical treatment in about two thirds of individuals. This is contrary to literature where surgery is the main mode of therapy.26 The explanation is that we are just building a new neurosurgery unit for pituitary glands over the last few years, and in the future, surgery of pituitary is supposed to improve, and early referral will be the best.

For prolactinoma, primary medical treatment was done in two thirds of patients, while it should be the main treatment of choice in more than 90%, as seen in previous literature.26

Malignant disease metastasizing to the pituitary is not observed in this study because they are not referred from Oncology Center in Basrah.

Study limitation
This study supposes to involve most of the pituitary disease patients in Basrah because the Center is a tertiary referral center. However, due to referral bias among some neurosurgeons and gynecologists, we cannot guarantee that the data includes all patients with this condition in Basrah.

Conclusion
Pituitary adenomas constituted the bulk of pituitary disease in patients treated at the FDEMC, Basrah. Growth hormone secreting adenoma (acromegaly) is the most frequent adenoma followed by NFPA and prolactinoma due to referral bias. A change in the practice of adenoma treatment is needed.

The study by Mansour AA et al. is an important contribution to the limited pituitary research in the middle East and North Africa (MENA) region.

The following points need further modifications/clarifications;

- Sellar and parasellar region lesions usually refers to structural abnormalities and do not necessarily include other pituitary pathologies like hyperprolactinemia and hypopituitarism. Therefore, I suggest using the term "pituitary disorders" instead; more comprehensive.

- The inclusion of patients needs further clarifications in the "Method" section. what diagnoses where looked for?

- Pituitary adenoma includes all functioning and non-functioning pituitary tumors. In some part of the text, it was used separately from its subtype (see paragraph; Definition of variables). Maybe just typo.

- Table (2) needs to be simplified. The total number of patients should equal clearly equal 232. I suggest using 3-4 categories only; Sellar masses/abnormalities, Hyperprolactinemia, hypopituitarism and others.

- The "miscellaneous" cases need to be mentioned; what diagnoses are here?

- Table 3 the sum of patient with pituitary adenoma subtypes are not equal to the total number of cases.

- In the conclusion, "A change in the practice of adenoma treatment is needed" is very general. Based on the presented data, change in the management of GH secreting adenomas is more specific and relevant.

- Additional language editing will further enhance the manuscript.

Is the work clearly and accurately presented and does it cite the current literature?
Partly

**Is the study design appropriate and is the work technically sound?**
Yes

**Are sufficient details of methods and analysis provided to allow replication by others?**
Yes

**If applicable, is the statistical analysis and its interpretation appropriate?**
Yes

**Are all the source data underlying the results available to ensure full reproducibility?**
Yes

Table (2) needs to be simplified. The total number of patients should equal clearly equal 232. I suggest using 3-4 categories only: Sellar masses/abnormalities, Hyperprolactinemia, hypopituitarism and others. It's can't be 232 because some may have more than one diagnosis.

- The "miscellaneous" cases need to be mentioned; what diagnoses are here? Miscellaneous includes galactorrhea, hypogonadotropic hypogonadism, and acromegaloidism.

- Table 3 the sum of patient with pituitary adenoma subtypes are not equal to the total number of cases.

GH-secreting adenoma, 2 of them stain on biopsy for lactotroph cell
GH-secreting adenoma with hyperprolactinemia in 5 patients

- In the conclusion, "A change in the practice of adenoma treatment is needed" is very general. Based on the presented data, change in the management of GH secreting adenomas is more specific and relevant.

A change in the practice of pituitary adenoma treatment is needed.
All adenomas treatment needed reevaluation.

- Additional language editing will further enhance the manuscript.

Done

**Competing Interests:** No competing interests were disclosed.
English language edition is needed.

The discussion section described the study results in comparison with recent literature. Recent literature has been adequately addressed. The authors stated the limitation of their manuscript clearly. It would be interesting to provide some information on the prognosis of their study patients, both for surgically or medically treated patients.

The references are clearly presented and conform the current standards.

The tables are clearly written.

Minor comments: although the manuscript is well written, however some revision of the English text needs to done.
