Abstract

Background: Toxoplasmosis is a globally distributed parasitic disease. The present study aimed to estimate the prevalence and geographic distribution of toxoplasmosis, as well as assess the risk of animal contact in disease development and determine the percentage of toxoplasmosis-associated IgM and IgG seropositivity among different age groups. In addition, it aimed to estimate the proportion of toxoplasma IgM seropositivity among pregnancy trimesters.

Methods: A total of 500 pregnant women were included in this study. From each participant, a 5-ml venous blood sample was collected and centrifuged to obtain serum that was tested for Toxoplasma gondii IgM and IgG antibodies using immunochromatographic testing and ELISA.

Results: The overall seroprevalence of toxoplasmosis was 24.8%, with rates of acute infection of 8%. Among positive cases in every trimester, 54.34% of first trimester positive cases had a serologic marker of acute toxoplasmosis. Out of the 40 pregnant women with previous history of cow/buffalo contact and toxoplasmosis, 40% were seropositive for toxoplasma IgM; and out of 30 women with prior history of dog contact, 16.66% had serological marker of acute toxoplasmosis.

Conclusions: In this study, there is a high prevalence of toxoplasmosis and contact with domestic animals is a risk factor for this illness. Therefore, it is necessary to test every pregnant women for toxoplasmosis and distinguish the type of infection, as well as the conduction of public health education programs to generate the awareness.

Introduction

Toxoplasmosis is a widely distributed zoonotic illness caused by *Toxoplasma gondii*, an obligate intracellular parasite. Globally, the distribution of this disease is extremely variable even inside the countries. In all host species, including humans, Toxoplasmosis is generally acquired either vertically from mother to fetus (congenital infection), or through ingestion of oocysts in contaminated food or water. Rarely, *T. gondii* can transmit through organ transplantation and the transfusion of infected blood. Following infection, the intestinal epithelium is the primary portal of entrance for *T. gondii*; next, it spreads to other tissues, where it can cause more severe pathogenesis. If toxoplasmosis is acquired during pregnancy, severe infection may develop, especially in immunocompromised individuals, such as those with defects in T-cell-mediated immunity. In patients with AIDS, toxoplasmosis may lead to severe, life-threatening disease. For example, cerebral focal lesions are caused by cerebral toxoplasmosis (CT) in HIV-infected patients.

The signs and symptoms of this illness are markedly divergent and range from asymptomatic to serious infection. This variation depends on several factors includes inoculums size, virulence of the strain of toxoplasma, the individual’s genetic background and the status of the immune system of the infected individual. In addition, since the organism has an affinity for muscular and neural tissues as well as the other visceral organs, many hosts harboring latent tissue cysts following toxoplasmosis.

Fetuses may acquire toxoplasmosis during delivery or through the placenta during pregnancy. Early infection of the fetus may cause severe damage, or either pre- or post-natal death. The clinical manifestation of congenital toxoplasmosis generally depends on the gestational stage, and can includes seizures, mental retardation, severe neurological defects, chorioretinitis, epilepsy and blindness.

Approximately 90% of pregnant women infected with *T. gondii* are asymptomatic, and recover spontaneously. Only a small percentage of pregnant women show the clinical symptoms of disease. In pregnant women, the clinical signs are no more severe than in non-pregnant women, and typically an influenza-like illness is seen after an incubation period of 5 to 18 days. Early diagnosis and treatment of mothers during pregnancy prevents fetal infection and minimizes the probability of complications.

Laboratory diagnosis of toxoplasmosis is usually performed by serological detection of *T. gondii*-specific IgG and IgM antibodies. Worldwide, the screening of *T. gondii* infection in pregnant women is preferably performed during the first trimester and subsequently every month or trimester in seronegative women, as applied in many countries.

Our study was undertaken to determine the prevalence and geographic distribution of toxoplasmosis. In addition, it sought to evaluate the role of animal contact in disease development among pregnant women through the serological detection of toxoplasma IgM and IgG antibodies, as well as to estimate the seropositivity of these antibodies among different age groups. It also attempted to identify the percentage of toxoplasma IgM seropositivity (indicative of acute infection) among different pregnancy trimesters.

Methods

This was a descriptive cross-sectional hospital-based study carried out in the District Head quarter Hospital (Mansehra, Hazara, Pakistan) and Ayub Medical Complex Hospital (Abbottabad, Khyber Pakhtunkhwa, Pakistan) over a period of 4 months (April to July 2015).

Study population and sample size

Our study included pregnant women of different trimesters, ages and ethnic groups who visited our study areas hospitals; the only eligibility criteria were pregnancy and visiting the hospitals in our study area. Patients were recruited by the researchers face-to-face. During this study duration, a total of 500 pregnant women (convenience sample) fulfilled the inclusion criteria. Out of the total of participants, 204 were recruited from Abbottabad and 296 from Mansehra district.

Laboratory analysis

A total of 5 ml venous blood was collected from each participant using a sterile syringe and transferred to a blood container without anticoagulant, allowed to clot at room temperature for 15 minutes, then centrifuged at 3000 rpm for 10 minutes to obtain serum, which was transferred into a 1.5-ml microcentrifuge tube and stored at −80°C for further analysis. In this study, every sample was screened and confirmed for toxoplasmosis through the serological tests.

Screening

All sera samples were screened for *T. gondii* IgG and IgM antibodies using Rapid Diagnostic immunochromatographic test (Tox IgG/IgM Rapid Test Dip strip, CTK BIOTECH, San Diego, USA) according to manufacturer instructions. In order to avoid false-positive results due to the incomplete specificity of the screening test, every positive sample was further subjected to confirmation step by ELISA. Each positive individual also answered a questionnaire concerning their age, trimester and whether they had been in recent contact with animals (Supplementary File 1).

Confirmation

Following screening, the positive samples (n=150) were further confirmed to toxoplasmosis using IgM and IgG ELISA kit (Monobind, San Diego, USA) according to the manufacturer’s protocol. The samples positive for *T. gondii* IgG titers indicated chronic infection and those with high IgM titers indicates recent or acute infection. All ELISA tests were performed in triplicate.

Ethical statement

Our study was approved by Hazara University. Further approval was provided by the Ayub Medical Complex Hospital. From every participant, written informed consent was obtained for conduction of the study. In addition, all the performed steps in this study were completely in accordance with Helsinki Declaration.
and the rules defined by the World Medical Association, including samples collection and processing.

**Statistical analysis**

The obtained results were analyzed by Graph Pad Prism 5 (Graph Pad Software, La Jolla, CA, USA). A $\chi^2$ test was involved to test the statistical differences in seropositivity and negativity of anti-toxoplasma antibodies among the participants of different study areas and gestational periods or those had/had no prior history of animal contact, at 95% level of significance. Moreover, ANOVA was tested the statistical difference of these antibodies among the participants of every age group. Difference was considered statistically significant when $P < 0.05$.

**Results**

**Seroprevalence of toxoplasmosis**

Out of 500 women, using ELISA the overall seroprevalence of toxoplasmosis was 24.8% (124/500). Statistically significant differences were observed between the seroprevalence of disease in Abbottabad and Mansehra district (Figure 1). In addition, the prevalence of toxoplasma antibodies among pregnant women revealed out of the total of 500 participants, only 8% had a serological marker of acute toxoplasmosis (Figure 2).

**Toxoplasma antibodies seropositivity among age group and gestational periods of positive cases**

Among the positive cases ($n=124$), the seropositivity of toxoplasma antibodies was shown to be statistically significant different among different age groups (Table 1). There was also a statistically significant difference in the seropositivity of toxoplasma IgM (indicating acute infection) between different gestational trimesters, the highest level of IgM seropositivity was observed in first trimester (54.34%) (Figure 3).

**Previous animal contact**

Our study findings revealed the previous animal contact is associated with toxoplasmosis (Table 2). In addition, the occurrence of Toxoplasmosis is also influenced by the species of animal to a statistically significant level. As we displayed in Table 2, out of 40 women with previous history of cow/buffalo contact, 40% were seropositive for toxoplasma IgM. As well as, out of 30 women with previous history of dog contact, 16.66% had serologic marker of acute toxoplasmosis.
Table 2. Frequency of acute toxoplasmosis (IgM-positive) in those with prior history of contact with domesticated animals.

| Type of animal | Prior history of animal contact, n | Toxoplasma IgM |  
|----------------|-----------------------------------|----------------|----------------|
|                |                                   | Seropositive   | Seronegative   |
| Cats           | 20                                | 15% (3/20)     | 85% (17/20)    |
| Goats          | 20                                | 35% (7/20)     | 65% (13/20)    |
| Dogs           | 30                                | 16.66% (5/30)  | 83.34% (25/30) |
| Cows/buffalos  | 40                                | 40% (16/40)    | 60% (24/40)    |
|                | **P value (seropositive vs seronegative)** |               | 0.038          |

Discussion

Toxoplasmosis in pregnancy can predispose the fetus to serious complications\(^8\). The fetus can be severely damaged when the infection is acquired during pregnancy\(^2\). Therefore, testing the serum of pregnant women for toxoplasma IgG and IgM is important to avoid intrauterine infection and complications. The current study was conducted on 500 blood samples collected from pregnant women in Mansehra and Abbottabad district of Pakistan, and examined for T. gondii IgM (acute infection) and IgG (chronic infection) antibodies. Out of the total of 500 pregnant women, 24.8% (124 women) had serologic marker of toxoplasmosis. Among the 124 positive cases, 54 were seropositive for toxoplasma IgG antibody, 40 cases for Toxo-IgM and 30 cases for both IgM and IgG antibody. In addition, out of 500 participants, 8% had a serologic marker of acute toxoplasmosis. In 2007, Obeed reported the prevalence of IgG (chronic infection) and IgM (acute infection) antibodies were 36% and 26.6%, respectively, which are greater than those seen in our study results\(^8\). In addition, the seroprevalence of toxoplasmosis in Saudi Arabia was reported as 21.8%\(^6\). In pregnant women from South Korea, a low prevalence rate was observed (0.79%)\(^2\), with rates of 20% reported in Finland\(^1\) and 24% in Prague\(^4\). These findings indicate the prevalence of toxoplasmosis is markedly different in different countries.

Moreover, our study revealed that the geographic distribution of toxoplasmosis is significantly different among the study areas. Out of the 296 participants analyzed from Mansehra and Abbottabad, the overall prevalence of toxoplasmosis was 15% and 38.7%, respectively. The higher prevalence in Abbottabad when compared with Mansehra may because Abbottabad is an area where agricultural practices are common, and domestic animals like cats and goats were generally kept in or near the homes. Thus, contact with these animals may be the main risk factor of the disease. In addition, low educational and socioeconomic level may have contributed.

In our study, a high percentage of IgM seropositivity was reported in the 1st trimester, which indicated a high prevalence of acute toxoplasmosis or recent infection in this trimester compared with the others. Furthermore, as reported in this study, there is a mild difference in the seropositivity of toxoplasma antibodies among age groups, which requires further study to assess whether, is there any significant association exists between toxoplasmosis and age.

Usually T. gondii does not cause clinical illness in the majority of animal species\(^8\). Human often acquire this infection from animals by ingestion of improperly cooked or raw animal meat, or via consumption of contaminated food and water with animals waste\(^8\). However, there is a need for detailed knowledge about the risk factors of toxoplasmosis. Previously, it was reported that there are some of risk factors are associated with toxoplasmosis, such as owning cats\(^7\). Our study found that a considerable percentage of acute toxoplasmosis-infected women had a previous history of close contact with animals; for example, 15% had the history of contact with cats, 16.66% with dogs, 35% with goats and 40% with cows/buffalos. These results indicate that contact with domestic animals carry a risk for this disease. Similar results are also reported by many studies\(^8,9\).

In this study, a high prevalence of toxoplasmosis was revealed. Lack of awareness together with contact with domestic animals are potential risk factors in Mansehra and Abbottabad district of Pakistan. Moreover, in the first and second trimester of pregnancy, the prevalence of acute toxoplasmosis seems to be higher compare with third. Thus it is necessary to test every pregnant women for toxoplasmosis and distinguish the type of infection. In addition, urgent treatment and medicine is essential to decrease the risk of intra-uterine infection and congenital toxoplasmosis. Additionally, there is a need to conduct public health education to create greater awareness about the disease, its transmission, symptoms, and prevention. In addition, screening of T. gondii infection and maternal care should be considered as the main stratagem to reduce the risks of congenital toxoplasmosis.

Data availability

Dataset 1. Raw data associated with this study. The results of immunochromatographic and ELISA screening, and history of animal contact are included. DOI: https://doi.org/10.5256/f1000research.15344.d224335

Asghar Fazaeli
Department of Medical Parasitology & Mycology, School of Medicine, Zanjan University of Medical Sciences, Zanjan, Iran

The manuscript is written in a good structure and presents useful data including the rate of anti-\textit{Toxoplasma} antibodies (IgG and IgM) in sera of pregnant women referred to hospitals of two districts in Pakistan. The manuscript however requires some corrections and modifications as follows:

1. The authors should consider that “toxoplasmosis” is not necessarily “illness or disease” as such they have mentioned in many parts of the manuscript. Toxoplasmosis is an infection which is mostly latent and does not lead to disease or illness in most of immunocompetent individuals. Also, some other issues in the Introduction are scientifically susceptible, e.g. toxoplasma acquisition in fetuses during delivery (mentioned in the 3rd paragraph of the Introduction); to my knowledge, this issue is not documented in the literature.

2. The basis of data arrangement, analysis and discussion about percentage of \textit{Toxoplasma gondii} antibodies in different age groups (Table 1) is not valid. For this issue, all 500 study cases must be primarily divided into different age groups, then the percentage of seropositivity (IgG, IgM, IgG+IgM) in all initial samples of each group should be calculated and consequently compared and analyzed.

3. There is no scientific reason to indicate possible relation between \textit{Toxoplasma} infection and contact with animals like caw, buffalo, goats, and dogs, except for cats which are a definitive host of \textit{Toxoplasma} and shed oocysts. The only way of passing \textit{Toxoplasma} infection from these animals to humans, is ingestion of undercooked meats or rarely through contact of open wounds with meats contaminated with bradyziotes, but not other types of contact with these animals or their wastes. So, this variable (animal contact) is not wise to be included in the manuscript and is recommended to be removed from all parts of the manuscript.

4. Miss-citation is the case for some \textit{Toxoplasma} facts in the manuscript. For example, cerebral toxoplasmosis is referred to Kristiah (2009), which is not the right citation; while it was originally reported and discussed by other researchers, i.e. Luft and Remington (1988\textsuperscript{1}) and Luft and

5. English writing correction is required in some parts of the manuscript text.

Dear Dr. Asghar Fazaeli,

Most of your suggestions have been addressed in Version 2, while we didn't address points 2 and 3 due to the following reasons:
1. Because we aimed to estimate the percentage of toxoplasma antibodies seropositivity among positive cases. Therefore, we calculate them by dividing the frequency of Ab seropositivity/Number of positive cases.
2. Because toxoplasmosis is a zoonotic disease, thus it can transmit to humans from animals as we mentioned in Version 1. In addition, in past research, scholars have found that there is an association of cat contact with disease development, while the association of other...
kinds of animals with disease is poorly understood. Therefore, we aimed to evaluate the role of different kinds of animals in disease development.

Thank you.

**Competing Interests:** No competing interests were disclosed.

This article has studied toxoplasmosis, which is considered as one of the most common causes of abortion, stillbirth, intrauterine death, and congenital abnormalities. In addition, it’s a globally distributed disease.

The paper is well designed and clearly written; the results were presented accurately and the conclusion is supported by study findings. In my opinion, it’s perfect and scientifically acceptable. However for further improvement of the article, the authors should revise the English grammar.
