Abstract
Drought stress is the most important abiotic stress that constrains crop production and reduces yield drastically. The germplasm of most of the cultivated crops possesses numerous unknown drought stress tolerant genes. Moreover, there are many reports suggesting that the wild species of most of the modern cultivars have abiotic stress tolerant genes. Due to climate change and population booms, food security has become a global issue. To develop drought tolerant crop varieties knowledge of various genes involved in drought stress is required. Different reverse genetic approaches such as virus-induced gene silencing (VIGS), clustered regularly interspace short palindromic repeat (CRISPR), targeting induced local lesions in genomes (TILLING) and expressed sequence tags (ESTs) have been used extensively to study the functionality of different genes involved in response to drought stress. In this review, we described the contributions of different techniques of functional genomics in the study of drought tolerant genes.

Introduction
Nowadays, global food security has become a major challenge due to the extreme changes to the climate and increases in the global population\(^1\). Therefore, plants are growing under various kinds of unfavourable environmental stresses such as drought, salinity, heat, cold and oxidative stresses which are retarding the growth and yield\(^2\). Of these, drought stress is the most predominant abiotic stress making this situation worse. Over the last decade, climate change has been increasing the frequency of drought conditions and reduced the crop yield (Table 1) by affecting the basic plant growth processes such as seed germination, photosynthesis, source sink relationships, turgor pressure, cell division and elongation, enzyme activities, and secondary metabolites production\(^2\)\(^3\)\(^4\)\(^5\). In addition, drought can also increase the production and accumulation of reactive oxygen species (ROS) in plants which leads to oxidative stress too\(^25\)\(^26\). Several genes that express under drought conditions are involved in the regulation of all these processes and pathways. In recent years, many drought tolerant genes have been identified in major food crops and still there are numerous genes taking part in drought stress whose functions are unknown. With the help of available genomic and transcriptomic data reverse genetic approaches accelerated the investigations of gene function under different abiotic stresses\(^27\).

From the perspective of crop improvement, transgenic approaches have been successfully used in many crops. However, development of stable transgenic lines is relatively expensive, time consuming and a laborious task. Moreover, it is not successful in many cultivated crops and slows down the investigations into specific gene\(^28\). In contrast, there are several techniques available for the study of these genes which give prompt results and have other advantages over transgenic techniques for analysis of target gene(s) such as virus-induced gene silencing (VIGS), clustered regularly interspaced short palindromic repeat (CRISPR)-Cas9 system, targeting induced local lesions in genomes (TILLING) and expressed sequence tags (ESTs)\(^29\)\(^30\)\(^31\)\(^32\).

VIGS
It is a simple, rapid, reliable and cost-effective post-transcriptional gene silencing (PTGS) technique for the study of endogenous genes. It is a powerful tool for the mining and study of genes involved in drought tolerance (Table 2). In VIGS a 200–400bp long fragment of the target gene is selected and cloned into a

viral vector which infects the plant and triggers the silencing of that particular gene\textsuperscript{29,35}. For efficient gene silencing the selection of the target fragment is very crucial. This technology can be used for forward and reverse genetics for both monocotyledonous and dicotyledonous plants\textsuperscript{46,57}. There is no requirement of stable plant transformants in VIGS technology\textsuperscript{53}. Moreover, a number of different genes can be studied simultaneously and a specific target can also be silenced individually through this technology\textsuperscript{59,60}. Many VIGS vectors have been developed for different crops by modifying plant viruses and have been used successfully for the functional study of genes expressed under drought stress\textsuperscript{31-44}. These VIGS vectors along with the target gene can be inoculated into the plants by different methods such as agrodrench, needleless syringe inoculation, agro inoculation, prick inoculation, and biolistic inoculation\textsuperscript{56,65}.

Plants have adopted many molecular mechanisms to withstand different abiotic stress, and a number of stress related genes get stimulated under stress conditions\textsuperscript{46,67}. Among them, MAPKs (Mitogen Activated Protein Kinases) are the most important enzymes for the plant growth and development and also play an important role in signal transduction under extreme conditions\textsuperscript{40-42}. The role of different MAPKs under drought stress has been studied through VIGS technology. The silencing of genes SpMAPK1, SpMAPK2, SpMAPK3 in \textit{Solanum pimpinellifolium}, SIMPK in \textit{Solanum Lycopersicum} and \textit{GhMKK3} in \textit{Gossypium hirsutum} reduced the drought tolerance in silenced plants\textsuperscript{41,42,51}.

In addition, various transcriptional factors regulate the plants behaviour in response to environmental conditions\textsuperscript{71}. The WRKYs transcription factors play crucial role in the plant development under drought stress\textsuperscript{44}. In cotton the VIGS of \textit{GhWRKY27a} enhanced the tolerance against drought stress\textsuperscript{52}. Further, another family of transcriptional factor, NAC, plays an important role under drought\textsuperscript{75}. Silencing of the \textit{GhNAC79} and \textit{JUB1} genes in cotton and tomato respectively made the plants more sensitive to drought\textsuperscript{43,44}. In addition, \textit{PbrMYB21} gene belonging to MYB family of transcription factors (TFs) studied in \textit{Pyrus betulaefolia}. The \textit{PbrMYB21} silenced plants exhibited decreased drought tolerance in comparison to control plants\textsuperscript{53}. Beside these, SR/CAMTA proteins from a small family of TFs and silencing of \textit{SISRIL} and \textit{SIGRX1} genes from this resulted in decreased tolerance against drought stress in tomato\textsuperscript{43,51}.

Beside these, autophagy, a protein degradation process induced in plants in response to environmental stimuli, has been reported to be involved due to the involvement of autophagy-related genes (ATG) under drought stress\textsuperscript{56-70}. The \textit{ATG8} gene in wheat and \textit{ATG6} and its orthologs get induced in wheat, rice and barley in response to multiple abiotic stresses. barley stripe mosaic virus (BSMV) based VIGS system was used for their functionality under drought stress. The results indicated the active participation of \textit{ATG} genes in various survival mechanisms used by plants under drought\textsuperscript{49,59}. In spite of these, many drought tolerant genes have been reported in weeds and also wild species of major cultivars. For instance, \textit{ApdRI15} gene in a weed named, \textit{Alternanthera philoxeroides} has been identified as a drought tolerant gene through VIGS\textsuperscript{57}.

### Expressed sequence tags (ESTs)

It is a sequence based technique that can be used to identify or study genes. ESTs can be generated from cDNA libraries\textsuperscript{50}. Functional studies of specific genes using this technique, can provide results in a cost-effective manner\textsuperscript{51}. Large scale EST sequencing has been performed in various crops and in several crops it is in progress. Millions of ESTs of different crops are available at Expressed Sequence Tags Database of National Center of Biotechnology Information. To identify drought stress responsive genes, first cDNA libraries are developed from plants growing under stressed conditions or from drought challenged tissues of drought responsive genotypes. Then by sequencing the clones ESTs can be identified\textsuperscript{50,52}. ESTs provide high quality transcripts for investigation of genes as functional markers under stress conditions. During the last two decades, drought responsive genes have been identified and studied by ESTs in a number of crops such as common beans\textsuperscript{41}, barley\textsuperscript{42}, \textit{GhMKK3} in \textit{Gossypium hirsutum} and \textit{ApdRI15} gene belonging to \textit{Solanum pimpinellifolium} reduced the drought tolerance in silenced plants\textsuperscript{41,42,51}.

### TILLING

With the advancements in high-throughput techniques genomes of a large number of crops are available now which present a number of new opportunities for the application of traditional mutation based reverse genetic techniques\textsuperscript{105}. TILLING is a nontransgenic method used to study allelic variations in the target gene in a mutant population and the effect of the mutant gene is studied from the changes in plant phenotypes\textsuperscript{20,56,107}. It is a quick and comparatively cheap method for the screening of single nucleotide polymorphisms (SNP) in the target sequence. These point mutations in the target genes can be identified by PCR\textsuperscript{105,108}. Moreover, this technique is applicable to any plant species whose genome sequence is available, regardless of its ploidy levels. In TILLING, to induce mutations in plant genome chemical mutagens are used that generated random mutations\textsuperscript{105}. In most of the experiments, to generate the TILLING population ethymethansulfonate (EMS) is used as a mutagen\textsuperscript{10}. However, to study the polymorphism developed, due to environmental conditions, a modified technique called as EcoTILLING has been developed. It seems a more promising strategy to study the genes related to abiotic stresses\textsuperscript{106,110}.

### CRISPR Technology

CRISPR (Clustered Regularly Interspaced Short Palindromic Repeat)/ CRISPR-associated nuclease protein (Cas) 9 technology based upon plant antiviral defense mechanisms, offered various new opportunities for researchers. It is relatively simple, easy, less cytotoxic and very efficient targeted genome editing technology in comparison to traditional techniques used for the same purpose\textsuperscript{111,112}. CRISPR/CAS9 based gene editing technology has become common practice in various labs. It involves the use of the CAS9 endonuclease, originally derived from \textit{Streptococcus pyogenes}, and a guide RNA which leads CAS9 to the target sequence working together and generate double stranded DNA breaks which are later repaired by the error prone non-homologous end joining (NHEJ) method or by the homology directed repair (HDR) pathway\textsuperscript{35,113,114}. Recently, this technology
has been extensively used for crop improvement\textsuperscript{11,15–120}. This system has been successfully used to study the genes involved in drought stress (Table 3) in model plant Arabidopsis\textsuperscript{12} and also in a number of crops such as soybean, maize\textsuperscript{14,122}, rice\textsuperscript{12}, tomato\textsuperscript{124}.

### Conclusion and future perspectives

Severe droughts are becoming more common every year and are reducing crop yield considerably. There is an urgent need for drought tolerant varieties. Breeding and transgenic approaches could solve this problem but the knowledge of molecular mechanisms and genes taking part in drought tolerance is essential. Several reverse genetic techniques have proved their potential in many crops and some are still evolving. During the last decade, the genomes of several crops were successfully sequenced, various new VIGS systems have been developed for different crops\textsuperscript{13–131} and CRISPR has become the most powerful tool for genome editing\textsuperscript{132–134}. Thus, these techniques can play a pivotal role in crop improvement and can contribute highly in the development of drought tolerant varieties.

The review entitled “Milestones achieved in response to drought stress through reverse genetic approaches” by Singh et al., presents recent advances in understanding the response of drought stress in crop plants using reverse genetic technologies. It is well known that drought stress is major concern in the era of climate change. Therefore, it is important to address the recent updates on drought stress response in crop plants to scientific communities. The review article is written and organized very well but minor points need to be taken care.

1. Authors have explained several techniques available to study the functionality of different genes involved in response to drought stress but should also include the advantages of these techniques in monocots/dicots.

2. In VIGS, authors should explain the functional analysis of DREB transcription factors using VIGS technology citing some latest references.

3. In ESTs analysis, authors should include the analysis of drought responsive ESTs generated through chemical priming studied in crop plants.

Is the topic of the review discussed comprehensively in the context of the current literature?
Yes

Are all factual statements correct and adequately supported by citations?
Partly

Is the review written in accessible language?
Yes

Are the conclusions drawn appropriate in the context of the current research literature?
Yes

Competing Interests: No competing interests were disclosed.
Reviewer Expertise: Plant Molecular Biology

I have read this submission. I believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

Reviewer Report 31 October 2018

Title: Ok, it represents the article well
Abstract: Ok, it provide the central idea about the article precisely. However, authors can expand it a little more.
Keywords: Authors should arrange them alphabetically
Introduction: At the end of first paragraph, authors suggested about available transcriptomic data. I believe there they can add some references of available transcriptomes related to the topic. Overall, it has been written fine.
VIGS: Authors provided all the required information related to this technology. However, there are some bioinformatics tools, which helps in the selection of target fragment within the gene. They can add these too.
Expressed sequence tags (ESTs): Ok
TILLING: Ok
CRISPR Technology: Ok
Conclusion: Ok, Nicely written.

To summarize, the review by Singh et al. presents our current knowledge of many genes deciphered by reverse genetic technologies: VIGS, EST, TILLING and CRISPR. The tables represents ample amount of information in a well-organised way. Overall, the Review provides a useful compilation of subject matter related to addressed topic in a coherent way.

Is the topic of the review discussed comprehensively in the context of the current literature?
Partly

Are all factual statements correct and adequately supported by citations?
Yes

Is the review written in accessible language?
Yes

Are the conclusions drawn appropriate in the context of the current research literature?
Yes
**Competing Interests:** No competing interests were disclosed.

I have read this submission. I believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

The benefits of publishing with F1000Research:

- Your article is published within days, with no editorial bias
- You can publish traditional articles, null/negative results, case reports, data notes and more
- The peer review process is transparent and collaborative
- Your article is indexed in PubMed after passing peer review
- Dedicated customer support at every stage

For pre-submission enquiries, contact research@f1000.com
