Abstract
Background The relationship between handedness and digital dermatoglyphic patterns has never been investigated in the Sinhalese population. The goal of this study is to establish the above mentioned relationship, which would positively aid personal identification.

Findings One hundred forty Sinhalese students (70 right-handed and 70 left-handed) were studied for their digital dermatoglyphic pattern distribution. The results show that a statistically significant correlation exists for; digit 5 (Ulnar loop; P= 0.0449 and radial loop; P= 0.0248 by Fisher’s exact test) of the right hand in female, digit 1 (radial loop; P=0.0248 by Fisher’s exact test) and digit 2 (Ulnar loop; P=0.0306) of the left hand in females, digit 3 (Ulnar loop; P= 0.0486 and whorl; P= 0.0356 by Fisher’s exact test) and digit 4 (Ulnar loop; P= 0.0449 and whorl; P= 0.0301 by Fisher’s exact test) of the right hand in males, digit 4 (whorl; P=0.0160 by Fisher’s exact test) of the left hand in males.

Conclusions Statistically significant differences in handedness and digital dermatoglyphic patterns were evident among Sinhalese people. Further study with a larger sample size is recommended.

Introduction

Fingerprints (digital dermatoglyphics) are a unique form of evidence that greatly contribute towards personal identification in forensic science. Because they are unique for each individual and are strongly influenced by genetics, they also perform a significant role in anthropology, human genetics, ethnology and medicine. They are characterized by alternating strips of raised friction ridges and grooves present in a variety of patterns. These patterns start to develop between the 5th and 6th week of intrauterine life, and are fully formed by the 21st week. These patterns do not change throughout postnatal life and their development is determined by several genes.

Handedness (i.e. hand dominance) is defined as the uneven distribution of fine motor skills between the left and right hand. Determination of the handedness of both the assailant and the victim are important in various aspects of forensic science, including personal identification. Hence, establishing the relationship between handedness and digital dermatoglyphics will aid forensic identification.

To date, scarce amount of studies have investigated whether there is a correlation between handedness and digital dermatoglyphics. In 1940 Cummins discovered a slight association in the sex differences of asymmetrical occurrence of dermatoglyphic patterns. Cromwell and Rife in 1942 found that left-handers are characterized by slightly less bimanual asymmetry than right-handers among Caucasian school children in southwestern Ohio. In 1943 Rife found associations characteristic of autosomal linkage between the whorl frequencies on the fingers and handedness among descended from northern European stock. In 1994 Coren reported an increased number of arches, fewer whorls in left-handers as compared to the right-handers among Canadians. Cho in 2010 found significant difference of dermatoglyphics patterns on digit 3, 4 and 5 among Koreans. None have investigated this association in a Sinhalese population (an Indo-Aryan ethnic group who are native to the island of Sri Lanka). The main goal of the current study is to determine the relationship between handedness and digital dermatoglyphics in a sample of Sinhalese population.

Methods

The study was conducted at the Department of Forensic Medicine, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka. Ethical clearance for this study was obtained from the Ethical Clearance Committee of the institute. Total of hundred forty Sinhalese students (70 females, 70 males) who gave informed written consent were included in the study. Ages of females ranged between 21 and 28 years (mean ± s.d. = 24.40 ± 1.82 years) and males ranged from 22 and 28 years (mean ± s.d. = 24.67 ± 1.92 years). Firstly, handedness was assessed using the Edinburgh Handedness Inventory. This required participants to demonstrate 10 unimanual tasks (preferred hand for writing, drawing, throwing, striking a match, opening a box, holding scissors, holding a toothbrush, holding a spoon, holding a broom and holding a knife). These tasks are common to Sri Lankans and they were advised to state the degree of preference for the hand used in each case as either strong (two points) or weak (one point). The handedness measure was calculated by subtracting the score for the left hand from the score for the right hand, dividing by the sum of both, and multiplying it by 100, providing an absolute range from -100 (completely left-handed) to +100 (completely right-handed). We recruited 50 predominant right-handers and 50 predominant left-handers after evaluating handedness.

All eligible students were asked to wash their hands thoroughly to remove dirt and dry them before obtaining fingerprints. Rolled prints were obtained by the ink and paper method as described by Cummins and Midlo. The subject was asked to roll their finger from the radial side to the ulnar side on an ink pad and then transfer their fingerprints in the same manner onto the allocated area of a double sheet of plain A4 paper (Figure 1). In this way, fingerprints for all the ten fingers were obtained for each individual. Digits are numbered as follows; digit 1 (thumb), digit 2 (index finger), digit 3 (middle finger), digit 4 (ring finger) and digit 5 (little finger).

Digital dermatoglyphic patterns (Figure 2) were classified as follows; ulnar loop, radial loop, whorl (double loop whorl, plain whorl, central pocket loop and accidental whorl were counted as whorl) and arch (plain arch and tented arch were counted as arch). In this way, fingerprints of all the ten fingers were obtained for each individual.

Analysis was carried out using GraphPad Prism 5 software (version 5.03 for Windows; GraphPad Software, San Diego California USA). Descriptive statistics were used to express the data. Correlations between handedness and digital dermatoglyphics were evaluated by a two-sided Fisher’s exact test. P values less than 0.05 were considered statistically significant.

Results

In this study we observed the handedness-wise digital dermatoglyphics pattern distribution of 140 individuals (70 left-handed [35 females, 35 males] and 70 right-handed [35 males, 35 females]).

Figure 1. Method for obtaining fingerprints. A and B show the rolling of the finger from the radial side to ulnar side on an ink pad. C and D show the transference of fingerprints onto the allocated area of the paper.
Handedness wise differences of digital prints in females

Right hand. Table 1 shows the digital dermatoglyphic pattern distribution of the right hand in females. On the digit 3 of right hand of right-handed students found to have more ulnar loop (74%) compared to left handers (57%) and on the digit 5 of right hand of right-handed students found to have more ulnar loop (69%) compared to left handers (49%). On the digit 2 of left hand of left-handed students found to have more ulnar loop (63%) compared to left handers (34%), followed by 40% whorl on right handed compared to 23% whorl in left handed. On the digit 1 of left hand of right-handed individuals found to have more whorl (46%) compared to left handers (29%), followed by 17% radial loop on left handed compared to 0% radial loop in right handed. A statistically significant correlation was observed in digital dermatoglyphic patterns between right and left-handed people for digit 5 (Ulnar loop; \(P = 0.0449\) and radial loop; \(P = 0.0248\) by Fisher’s exact test).

Left hand. Table 2 shows the digital dermatoglyphic pattern distribution of the left hand in females. On the digit 3 of left hand of right-handed students found to have more ulnar loop (71%) compared to left handers (54%) and on the digit 5 of left hand of right-handed students found to have more ulnar loop (69%) compared to left handers (49%). On the digit 2 of left hand of left-handed students found to have more ulnar loop (63%) compared to left handers (34%), followed by 40% whorl on right handed compared to 23% whorl in left handed. On the digit 1 of left hand of right-handed individuals found to have more whorl (46%) compared to left handers (29%), followed by 17% radial loop on left handed compared to 0% radial loop in right handed. A statistically significant correlation was observed in digital dermatoglyphic patterns between right and left-handed people for digit 1 (Radial loop; \(P = 0.0248\) by Fisher’s exact test) and digit 2 (Ulnar loop; \(P = 0.0306\) by Fisher’s exact test).

Handedness wise differences of digital prints in males

Right hand. Table 3 shows the digital dermatoglyphic pattern distribution of the right hand in males. On the digit 3 of right hand of right-handed students found to have more ulnar loop (74%) compared to left handers (49%) and on the digit 4 of right hand of right-handed students found to have more ulnar loop (49%) compared to left handers (23%). On the digit 3 of right hand of left-handed students found to have more whorl (43%) compared to right-handers (17%) and on the digit 4 of right hand of left-handed students found to have more whorl (69%) compared to right handers (40%). Radial loop and arch pattern have not shown significant difference. A statistically significant correlation was observed in digital dermatoglyphic patterns between right and left-handed people for digit 3 (Ulnar loop; \(P = 0.0486\) and whorl; \(P = 0.0356\) by Fisher’s exact test) and digit 4 (Ulnar loop; \(P = 0.0449\) and whorl; \(P = 0.0301\) by Fisher’s exact test).

Left hand. Table 4 shows the digital dermatoglyphic pattern distribution of the left hand in males. On the digit 2 of left hand of left-handed students found to have more ulnar loop (63%) compared to right handers (43%) and on the digit 4 of left hand of right-handed students found to have more ulnar loop (60%) compared to left handers (37%). Radial loop, whorl and arch pattern have not shown significant difference. A statistically significant correlation was observed in digital dermatoglyphic patterns between right and left-handed people for digit 4 (0.016 by Fisher’s exact test).

The percentage of digital dermatoglyphics pattern distributions for both hands in male and female Sinhalese are shown in Figure 3 and Figure 4.

Discussion

It has been affirmed that the digital dermatoglyphic pattern of the skin is unique and unchallengeable for an individual. This is valuable as a means of identification. In this study, effort has been made to study the relationship between dermatoglyphic and handedness in 140 Sinhalese students.

The results showed that a statistically significant correlation exists in digit 5 of the right hand while digit 1 and digit 2 of left hand in female. In males digit 3 and digit 4 of right hand and digit 4 of left hand showed a statistically significant correlation.

In the past, few studies have been conducted on different ethnic groups with the idea of establishing a relationship between handedness and dermatoglyphic pattern. Results of some studies are in line with the present study.

In their study on Caucasian school children in southwestern Ohio, Cromwell and Rife (1942) observed a slightly higher frequency of whorls (1.3%) on left ring fingers (digit 4) of left-handers than of right-handers. Whorls were absent on the right ring finger of both right- and left-handers. They further observed that the incidence of arches only on digit 3 of right hands shows highly significant differences between left-handers and right-handers (P<0.001).

Coren (1994) in his study on Canadians found that left-handers were more likely to have arches and radial loops, while fewer whorls than right-handers. The correlation of handedness and digital dermatoglyphics was most marked on the left hand, which showed significant differences on four digits except digit 1. On the right hand, handedness was associated with a digital dermatoglyphics patterns only on digit 4.

Cho (2010), in their study on Koreans, found that both hands of left handers exhibited more arch and ulnar loop types than the right-handers and less whorl and radial loop types than the right-handers. The digital dermatoglyphic pattern of digit 3, digit 4 and digit 5 of the left hand showed a statistically significant relationship between left- and right-handed people.

In Karev’s study on Bulgarian individuals, he found that whorls were significantly less frequent, and ulnar loops significantly more frequent in all digits for right-handed people when compared to
left-handed people. The ulnar fluctuating asymmetries of digits 1 and 4 showed a highly significant relationship with handedness.

Rife (1955)\(^4\), in his study on students at Ohio State University, USA, observed that arches were more common on the left middle finger of right-handed students than left-handed students. Left-handedness has a frequency of about 10% in the general population with a slightly higher frequency in the male population compared to the female population\(^1,2\). In our study we analyzed dermatoglyphics pattern of 70 left hander’s (35 males, 35 females) and compared it with right hander’s (35 males, 35 females). Gender wise differences in digital dermatoglyphics patterns have been established for now and then\(^3\). We compared handedness wise difference of dermatoglyphics pattern in right and left hand of both male and female Sinhalese separately.

The major limitation of our study is the small sample size. Despite the small sample size, it exhibited a significant handedness wise difference of dermatoglyphics among Sinhalese. Additional research involve large sample are needed to further confirm current findings.

**Conclusion**

The present study supports the hypothesis that handedness and digital dermatoglyphics are correlated in members of the Sinhalese population. Our results show that there is a statistically significant difference in fingerprint patterns between right- and left-handed people for digit 5 of the right hand and for digits 1 and 2 of the left hand in females, and digit 3 and digit 4 of the right hand and digit 4 of the left hand in males. The results of this study support the relationship between handedness and digital dermatoglyphics in the Sinhalese population. The results can be used as supporting evidence for personal identification.

**Author contributions**

BTBW was involved in study conception and design. BTBW and RMSGK assisted with data collection, study coordination and data analysis. Both authors were involved with drafting the manuscript. Both authors read and approved the final manuscript.

**Competing interests**

No relevant competing interests were disclosed.

**Grant information**

The author(s) declared that no grants were involved in supporting this work.

In the Methods section, the authors say: “We recruited 50 predominant right-handers and 50 predominant left-handers after evaluating handedness" but in the Results section they say “In this study we observed the handedness-wise digital dermatoglyphics pattern distribution of 140 individuals (70 lefthanded [35 females, 35 males] and 70 right-handed [35 males, 35 females])". The error should be corrected

Competing Interests: No competing interests were disclosed.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

✔️ Matea Zajc Petranović
Institute of Anthropology, Zagreb, Croatia

The article is clearly laid out and all the key elements are present. It was significantly improved after including previous reviewers' comments.

Competing Interests: No competing interests were disclosed.
I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

Author Response 01 Aug 2013

Buddhika Wijerathne, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Saliyapura, Sri Lanka

We would like to thank Matea Zajc Petranović for spending her valuable time to review the manuscript.

Competing Interests: No competing interests were disclosed.

The study was based on data from 100 individuals (50 left-handed [31 females, 19 males] and 50 right-handed [27 males, 23 females]). The greatest limitation of this study is the small sample size, as authors indicate; this size would be even smaller if the sample was analyzed by sex, as should have been done. The distribution of digital patterns presents sex differences in most of the samples analyzed, and so, the results cannot be accepted because they are affected by the effect of sex differences.

Competing Interests: No competing interests were disclosed.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.

Author Response 08 Jul 2013

Buddhika Wijerathne, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Saliyapura, Sri Lanka
We would like to thank Professor Esperanza Gutierrez Redomero for the valuable time spent reviewing our manuscript and the important comments she has made. We have attempted to address and incorporate most of the concerns that were raised in version 2 of our article.

**Competing Interests:** No competing interests were disclosed.

The benefits of publishing with F1000Research:

- Your article is published within days, with no editorial bias
- You can publish traditional articles, null/negative results, case reports, data notes and more
- The peer review process is transparent and collaborative
- Your article is indexed in PubMed after passing peer review
- Dedicated customer support at every stage

For pre-submission enquiries, contact research@f1000.com
