**Abstract**

**Introduction:** Despite of the recent advances in the adhesive dentistry, high possibility of microbial biofilm development at the resin restoration surfaces may lead to marginal gaps and recurrent caries. Degree of conversion of the dental adhesive represents a relative assessment to its quality, and a direct correlation with its mechanical behavior. This *in vitro* study was carried out to investigate the minimum inhibitory concentration of antimicrobial silver nanoparticles incorporated in two forms into the self-etch adhesive system and the effect of their incorporation on the degree of conversion of the self-etch adhesive.

**Methods:** Minimum Inhibitory Concentration of the self-etch adhesive system incorporated with nanosilver powder and solution against *Streptococcus mutans* was tested using an agar diffusion test. The effect of nanosilver incorporation (powder and ethanol-based solution) in the self-etch adhesive system on its degree of conversion was assessed using Attenuated Total Reflectance/ Fourier Transform Infra-Red spectrometer (ATR/ FTIR).

**Results:** The results showed that silver nanoparticles incorporation (powder or ethanol based at 12.5 μg/ml concentration) significantly increased the antibacterial efficacy of the self-etch adhesive against *Streptococcus mutans* (P < 0.05). Nanosilver powder possessed higher significant antibacterial effect when compared to silver ethanol based solution (P < 0.05). Degree of conversion of self-etch adhesive containing nanosilver powder showed non-significant difference from the control group (P > 0.05). In contrast, self-etch adhesive with nanosilver solution recorded significantly lower values when compared to the control or nanosilver powder group (P < 0.05).

**Conclusion:** The antibacterial efficacy of the adhesive system can be greatly potentiated with the addition of silver nanoparticles (12μg/mL concentration) especially the nanosilver powder. Incorporation of the antibacterial nanosilver powder in the adhesive system didn’t compromise the degree of conversion of the adhesive resin.

Introduction
Dental resin composite is a widely used restorative material that has superior aesthetic properties and strong bonding ability to the tooth structure in comparison to other restorative materials like amalgam. In spite of the recent advances in the dental adhesives, there is a high possibility of microbial biofilm development at the resin restoration surface, which may lead to marginal gap and recurrent caries.

Silver is an antimicrobial agent that has broad spectrum activity against gram positive and gram negative bacteria. Nanoparticles are insoluble particles smaller than 100 nm. Their unique size provides higher surface area, thus much more potent antimicrobial activity in comparison to the usual particles size. Silver nanoparticles can cause cell membrane disruption and damage of the bacterial DNA. Degree of conversion of the dental adhesive represents a relative assessment to its quality and directly correlates with its mechanical behavior. Proper polymerization of the dental adhesive can increase the longevity of the bonded restoration. Therefore, it seems valuable to investigate the minimum inhibitory concentration of silver nanoparticles incorporated in two forms into the self-etch adhesive system and their effect on the degree of conversion.

Methods
The materials, preparations, manufacturers, composition and batch numbers are listed in Table 1.

Incorporation of silver nanoparticles into the self-etch adhesive system
1 ml of ethanolic solution of silver nanoparticles was added to 5 ml of self-etch adhesive system and serially diluted. To produce the adhesive system with the nano-silver powder incorporated, it was accurately weighed first using a scale (AE Adam, Bradford, UK). The previously measured powder (1000 µg) was added to 1 ml of adhesive solution, sonicated in an ultrasonic mixer (Eumax model: UD100SH-3LQ, China) and was added to 1 ml of adhesive solution, sonicated in an ultrasonic mixer (Eumax model: UD100SH-3LQ, China) and was added to 1 ml of adhesive solution and directly correlates with its mechanical behavior. Proper polymerization of the dental adhesive can increase the longevity of the bonded restoration. Therefore, it seems valuable to investigate the minimum inhibitory concentration of silver nanoparticles incorporated in two forms into the self-etch adhesive system and their effect on the degree of conversion.

Determination of minimum inhibitory concentration (MIC) of self-etch adhesive system with and without nano-silver incorporation
The minimum inhibitory concentration (MIC) defined as the lowest concentration of nanosilver in micrograms per milliliter (µg/ml) that inhibits the growth of an organism. Tryptic soy agar medium; culture nutrient media for Streptococcus mutans (ATCC 25175) was poured in 10 petridish plates in a laminar flow (Telstar BIO- II-A, VWR Company, UK.). Streptococcus mutans strains; ATCC 25175 (Cairo MIRCEN, Faculty of agriculture, Ain Shams University, Egypt.) were cultured on Tryptic soy agar medium at 37°C for 24 hours.

10 petridish plates were punched by a cork-borer with a 6 mm diameter to produce rounded holes in each plate and the bacterial strain was applied equally on the agar plates. The specimens were grouped as $N_{1}$: Self-etch adhesive system + nanosilver solution and $N_{2}$: Self-etch adhesive system + nanosilver powder. Each agar plate contained 5 holes representing the five different concentrations of the nanosilver. For $N_{1}$ and $N_{2}$ groups; the self-etch adhesive system was serially diluted to produce 5 subgroups with different concentrations. $C_{1}$: 100 µg/ml, $C_{2}$: 50 µg/ml, $C_{3}$: 25 µg/ml, $C_{4}$: 12.5 µg/ml, and $C_{5}$: 6.25 µg/ml. The adhesive system without nanosilver incorporation was used as a control group ($N_{0}$).

200 µl of the adhesive agent was injected in each hole by micropipette and polymerized for 20 seconds using light emitting diode unit (Woodpecker Medical Instrument Company, Model LED. F; Model No. L14A0116F, China.) (Figure 1). The plates were incubated for 48 hours in the incubator at 37°C under completely anaerobic conditions (Shell lab Company, SM16, Canada). The diameter of bacterial inhibition zone halo of each adhesive was measured in millimeters using a ruler.
Degree of conversion measurement of the self-etch adhesive system with and without nanosilver incorporation

The specimens were prepared using a cylindrical Teflon mold surrounded by metallic ring (3mm diameter and 2mm height)\(^9\) (Figure 2). The mold was placed on a Mylar strip (Universal strips of acetate foil, Germany) that was placed on a clean flat glass slab. 200 µl of self-etch adhesive resin was injected in the hole of the mold using a micropipette then covered with the Mylar strip (to avoid the presence of oxygen inhibiting layer and pressed to obtain a uniform smooth specimen surface)\(^4,9\). The adhesive resin was cured in the presence of the top Mylar strip by LED device for 20 seconds according to manufacturer instructions. The light curing tip was applied perpendicular and with intimate contact with the top surface of the Mylar strip (Zero distance)\(^4\).

15 disc shaped specimens were prepared of self-etch adhesive system. The specimens were divided into 3 equal groups (n=5) according to the form of incorporated nanosilver (\(N_0\): Adhesive system without nanosilver, \(N_1\): Adhesive system+ nanosilver solution, \(N_2\): Adhesive system+ nanosilver powder). The concentration of the incorporated nanosilver was set according to the minimum inhibitory concentration (MIC) that was tested before.

Degree of conversion was measured using an Attenuated Total Reflectance/ Fourier Transform Infra-Red spectrometer (ATR/FTIR) (Vertex 70, Bruker Company, Germany)\(^1,10\). All the data were recorded and plotted on a special computer software (OPUS Bruker Spectroscopy Software, version 7, Germany) to draw the linear graphs from which the degree of conversion of each specimen was calculated.

Data statistically was described in terms of mean values and standard deviation (SD) using ANOVA test (IBM® SPSS® (SPSS Inc., IBM Corporation, NY, USA, Statistics Version 22 for Windows)).

Results

Agar Diffusion test

Mean ± SD measures of the diameter of inhibition zone (DIZ) were summarized in Table 2 and Table 3 and graphically drawn in Figure 3 (underlying data available from OSF\(^11\)). The largest zone of inhibition was at 100 µg/ml concentration of nanosilver powder while the smallest was at 6.25 µg/ml concentration of nanosilver solution.

NS; non-significant (p>0.05), *; significant (p<0.05).
All the concentrations recorded significantly higher DIZ when compared to the control group ($P \leq 0.05$) except $C_5$; 6.25µg/ml. The MIC of adhesive containing nanosilver (powder and solution form) was determined at 12.5 µgm/ml concentration. All the concentrations of nanosilver powder recorded significantly higher mean values of DIZ when compared to the different concentrations of nanosilver solution.

**Degree of conversion results**

(Mean ± SD) measures of degree of conversion in % were summarized in Table 4 and graphically presented in Figure 4. Groups of adhesive system with incorporated nanosilver solution ($26.14±4.47$ %) recorded a statistically significant lower degree of conversion when compared to control ($50.31±4.04$ %) and nanosilver powder ($47.72±4.47$ %) ($P \leq 0.001$). There was no significant difference in the degree of conversion between the control group and the group of the adhesive system containing nanosilver powder ($p \geq 0.05$).

**Discussion**

Self-etch adhesives exhibit limited antibacterial activity against Streptococcus mutans due to the presence of a low molecular weight monomer that possesses bacteriostatic action against Streptococcus mutans$^{12}$. The MIC for adhesive containing nanosilver in ethanol solution and powder was 12.5µg/ml concentration which was significantly different when compared to the control group ($P \leq 0.05$). These results confirmed the potential antibacterial effect of low concentrations of nanosilver. Adhesive resin with nanosilver powder at different concentrations showed significantly higher inhibition rates than that with nanosilver/ethanol dispersion.

The higher significant efficiency of nanosilver powder may be attributed to the presence of the ethanol as a dispersion medium for nanosilver solution that can act as a diluting agent of the adhesive system. That was observed at concentration 6.25 mg/ml in nanosilver solution as it showed lower significant value than the control group despite the presence of silver nanoparticles.

The nanosilver powder group recorded a statistically non-significant difference in the degree of conversion when compared to the control group. Presence of nanofillers in the adhesive system had no harmful effect on the degree of conversion$^{13}$.

Besides reducing of the amount of residual monomer, the nanoparticles size is less than the wavelength of the blue light of the curing units that allow the passage of the light without scattering; thus doesn’t affect the degree of conversion and the depth of cure of the adhesive system$^{14}$.

| | **Nanosilver Powder (N) 47.72±4.47** | **A** |  |

Means with the same letter within each row are not significantly different at $p=0.05$. NS= Non-significant, *=Significant
Groups of adhesive system with incorporated nanosilver solution recorded statistically significant lower degree of conversion when compared to the control and nanosilver powder ($p<0.05$). Presence of excessive amount of ethanol (Over 10% of the neat resin blend) lead to dilution of the adhesive resin, (decrease the percent of polymerized resin). Moreover it can cause physical separation of some reactive components of the adhesive resin with subsequent reduction of the degree of conversion. Previous research has attributed the negative effect of excess ethanol on the degree of conversion to its cooling effect (polymerization reaction is exothermic and the liberated heat increase the rate of conversion). Ethanol can absorb the liberated heat thus decrease the rate of polymerization and the degree of conversion of the adhesive resin.

There were no recorded studies evaluated the effect of nanosilver (powder form or ethanol based solution) incorporation in the self-etch adhesive system on the degree of conversion.

**Conclusion**

The antibacterial efficacy of the adhesive system can be greatly potentiated with the addition of silver nanoparticles (12µg/mL concentration) especially the nanosilver powder. Incorporation of the antibacterial nanosilver powder in the adhesive system didn’t compromise the degree of conversion of the adhesive resin.

Further investigation is required for assessing the mechanical behavior and chemical reactions of adhesive systems containing silver nanoparticles in short and long-term. It is also recommended to evaluate the antibacterial activity of adhesive system containing silver nanoparticles against dental plaque biofilm rather than single bacterial species.
