Abstract
Background: Knowledge management (KM) is a recipe for increasing performance and promoting innovation in tertiary institutions. However, some scholars argue that the Nigerian educational sector is yet to fully appreciate the importance of KM as their KM awareness level is still low. Since measurement is the basic foundation to accomplish success, this paper assesses the KM awareness level in tertiary institutions of south-west Nigeria.

Methods: We applied a survey method using a closed ended questionnaire administered to 50 participants from each of the 10 institutions measured by Likert scaling. Employing SPSS for data analysis, frequency count and percentage score were adopted to analyse the demographic data, and the research hypotheses were analysed with chi square test, Pearson chi square and bivariate correlation (Pearson) analysis.

Results: A positive relationship between awareness, current status and level of familiarity was noted. KM awareness level in the institutions is high even though there is a significant difference between the public and private universities, as well as between the students and academic staff.

Conclusions: Since an increase in the awareness level increases both current status and level of familiarity which often account for KM success, it is recommend that KM awareness level should continuously be improved upon in Nigerian tertiary institutions.

Introduction
KM is a process of coordinating, organising and making institutional or organisational knowledge available for knowledge creation, sharing, storage and reuse to achieve institutional aims and objectives. Managing the existing knowledge flow in tertiary institutions is essential. According to Kayıkçı and Ozan, knowledge is a powerful tool for organisational competition and therefore becomes significant to every industry including banking, education and governmental sectors. Knowledge generated should be properly managed to ensure its future availability. Therefore, tertiary institutions have moved beyond being merely a knowledge provider to students, to also curating current knowledge for future use. A number of these institutions now operate like business organisations and compete among themselves, with knowledge as their commodity. Tertiary institutions are centres for knowledge creation and sharing, and are regarded as knowledge business organisations that should devise means of gathering and disseminating knowledge for effective decision making. Therefore, institutions desiring higher performance must identify, capture and circulate valuable institutional knowledge for re-use.

Many studies including Demchig and Kidwell et al. have worked on the application of KM in tertiary institutions, claiming that it improves institutional capabilities in decision making and reduces the product development cycle time, as well as improving academic and administrative services. They argue that KM adoption and implementation by the institutions could result to exponential improvements in knowledge sharing, as it has a positive impact on academic research, curriculum development, student and alumni services, administrative services and strategic planning. Al-sulami, Rashid and Ali, claimed that the performance level of an institution can shoot up through the effective and efficient implementation of knowledge management. Similarly, it increases innovation giving institutions a competitive advantage over others.

KM is an emerging concept in developing countries with varying awareness and maturity levels. Charles & Nawe discovered that staff of Mbeya University of Science and Technology (MUST) in Tanzania were not fully aware of KM practices. Demchig conducted an assessment on level of KM maturity in Mongolian higher institutions using the Knowledge Management Capability Assessment (KMCA) model; it was revealed that maturity level of KM was in level one, indicating knowledge sharing was not discouraged in Mongolian higher institutions.

Yaakub, Othman & Youssif discovered that KM practices in Malaysian higher learning institutions is still very low, while Anvari et al. found the level of KM in Firoozabad Islamic Azad University to be below average. Although KM awareness and maturity level is yet to be fully investigated amongst Nigerian tertiary institutions in the southwest geo-political zone, several Nigerian authors have found that KM is has yet to be fully implemented in Nigerian tertiary institutions.

While the literature indicates KM awareness in most developing country institutions is low, a number of studies do not agree. Since the position is difficult to generalise due to socio-cultural differences, KM awareness in Nigerian institutions needs to be further investigated. Hence, we formulated the following four hypotheses to test awareness levels, as well as ascertaining the difference between KM awareness levels of the public and private institutions, as well as that of the academic staff and students.

Hypothesis: KM awareness level in universities in the southwest of Nigeria is high.

Hypothesis: There is significant difference in the KM awareness level between public and private institutions in southwest Nigeria.

Hypothesis: There is a relationship between awareness, current status and KM familiarity in the tertiary institution in the southwest of Nigeria.

Methods
This section discusses appropriate sampling methods employed as well as the instrumentations adopted, and reported following the STROBE reporting guidelines.

Sampling method
This study adopted both probability and non-probability sampling to examine the awareness level of KM in Nigerian tertiary institution. The research population frame is the 46 accredited universities in south west Nigeria while the total population is 550 comprising both academic staff and students of selected tertiary institutions in South West Nigeria. Stratified random sampling was adopted to select 11 universities out of 46 accredited universities only. The stratified random sampling used is as follows:

- Firstly the population was grouped into three strata - federal, state and private containing 7, 11, and 28 universities respectively.
- Secondly, systematic random sampling was used to select item from each stratum.
- Lastly, the size of each stratum was kept proportional to the sizes of the strata thereby resulting in picking two federal, three state and six private universities.

Purpose sampling was used to select the names of the 11 universities involved in the research from each of the stratum, as well as the participants consisting of academic staff and students from the selected universities. The student population outnumbers staff in every university therefore, the authors decided to gather a sample of students to staff at a ratio of 3:2. To avoid data overload and have a manageable sample size, a total number of 50 respondents (30 students and 20 members of academic staff) were selected from each university to arrive at 550 (50x11) sample size.

The questionnaire (see Extended data) was personally administered to the 10 universities involved as one university backed out from the research. The 10 universities involved in the research were five public (two federal, three state) and five private. A total number of 50 respondents were selected from each university and 500 questionnaires were administered out of...
which only 456 were returned and used for the analysis. The Ethical Committee of the University of South Africa issued an authorization memo to approve the questionnaire.

**Instrumentation**

Likert scaling was adopted to measure awareness levels in each institution. Questions on level of KM awareness were assigned a score 1 to 4 for ‘none’, ‘low’, ‘high’ and ‘very high’ respectively while questions on knowledge recognition were respectively tagged with score 1 to 4 for ‘strongly disagree’, ‘disagree’, ‘agree’ and ‘strongly agree’. Similarly, questions on current status were assigned score tags of 1 to 4 for ‘not in existence’, ‘on pipeline’, ‘developing’ and ‘matured’ respectively, while the level of familiarity were assigned a score ranging from 1 to 4 for ‘unaware’, ‘introductory’, ‘intermediate’ and ‘advance’ respectively.

To test the reliability of the research instrument, Cronbach’s alpha reliability test was conducted generating a result of 0.845, thereby confirming the consistency, reliability and acceptability of the factors used. Similarly, the questionnaire was pre-tested using two institutions different from those involved in the study. Administering 60 questionnaires on 30 participants from each institutions, responses and comments obtained helped to identify and address potential hitches prior to performing the actual research.

**Ethical consideration**

In line with UNISA research ethics policy, all participants had the study explained to them before their recruitment. All participants provided written informed consent to participate.

**Data analysis**

IBM Statistical Programme for Social Sciences version 21 was adopted for this data analysis. Descriptive statistics of frequency counts and percentage scores was employed to analyse the demographic data, while the participants’ responses were analysed using percentage count. Hypothesis 1 was analysed with one sample chi square test, hypotheses 2 and 3 were by Pearson chi square, and hypothesis 4 was by Spearman’s rho – a non-parametric correlations.

For both the chi square and Pearson correlation coefficient, a p value <0.05 (5% significant) as ruled below.

- **Rule 1** If the p value is greater than 0.05 (p>0.05) accept the null hypothesis
- **Rule 2** If the p value is less than 0.05 (p<0.05) accept the alternate hypothesis
- **Rule 3** 0.00<|r|<0.33 indicates weak relationship
- **Rule 4** 0.34<|r|<0.66 indicates moderate relationship
- **Rule 5** 0.67<|r|<1.0 indicates strong relationship

**Result**

**Demographic characteristics of the respondents**

Table 1 shows the demographic characteristics of the respondents. The total number of returned questionnaires was 456, 82% of the 500 questionnaires administered. Of these, 55% were male while 45% were female. Regarding the academic qualification of the respondent, the majority respondents were undergraduates (63%), follow by those with a master’s degree (19%), PhDs (9%) and Bachelor’s degree (9%). In terms of respondents’ status, the majority were students (67%), with academic staff making up 33% of the sample. Public universities constituted 55% while private universities made up 45% (Table 1 and Underlying data).

**Test of research hypotheses**

To test the KM awareness level in the sampled institutions, a one-sample chi square test was applied to hypothesis 1. KM awareness levels were defined as ‘none’, ‘low’, ‘high’ and ‘very high’ (Table 2). The expected N for all the variables was 114. The results show that the hypothesis was accepted with test statistics value 295.930, expected count of 114 and p value of 0.001.

To test for possible differences in KM awareness level between academic staff and students, a one-sample chi square test was also used to test the hypothesis 2. The hypothesis was accepted as the test statistics value obtained was 24.794, the expected count was 0.64 and p value of 0.001.

In terms of differences in KM awareness levels between public and private institutions, the outcome of the one sample chi square test on hypothesis 3 confirms the acceptance of the alternate hypothesis with chi square test value of 10.301, expected count of 0.64 and p value 0.001.

Pearson correlation was applied on hypothesis 4 to determine the correlation between the KM awareness level, KM current status and KM familiarity. The hypothesis was accepted as the p value was 0.001. The result as depicted on Table 3 shows that there is a moderate relationship between the variables (KM awareness level, KM current status and KM familiarity) with a correlation coefficient range (r) of 0.35 < |r| < 0.45.

Discussion and conclusion

Although KM implementation is important to tertiary institutions, assessment must come before implementation. This study was therefore conducted in the context of the current literature, the majority of which suggests that KM is still emerging in developing countries, and yet to be fully implemented in Nigeria.

The study investigated knowledge management awareness in Nigerian South-west tertiary institutions and addressed the relationship between awareness, familiarity and current status of KM level. It was discovered that there is significant difference in KM awareness level amongst the public and private universities. Awareness levels between academic staff and students is also significantly different, conforming with the findings of Krubu and Akuegwu and Nwue where heads of department were more involved in KM practice. This study also empirically provides evidence for correlation between the awareness, familiarity and current status of KM level. We found a positive relationship between awareness, current status and level of familiarity. This suggests that if awareness levels increase, more people/institutions will practice KM and its current status will improve thereby shifting the state from developing to maturing. Similarly, KM awareness levels in south west tertiary institution was found to be high, confirming the previous studies of Ohiorenoya and Eboreime and Oke, Ogunsemi and Adeeko. However, since KM awareness level in both the public and private institutions in the South West region in Nigeria is also high, this study concludes that Nigerian institutions recognise the importance of KM towards achieving institutional innovations and higher performance.

Further research may be needed to investigate the level of KM maturity and the relationship between KM and academic performance in Nigerian institutions.
