Abstract

Functional dependencies (FDs) and candidate keys are essential for table decomposition, database normalization, and data cleansing. In this paper, we present FDTool, a command line Python application to discover minimal FDs in tabular datasets and infer equivalent attribute sets and candidate keys from them. The runtime and memory costs associated with seven published FD discovery algorithms are given with an overview of their theoretical foundations. Previous research establishes that FD_Mine is the most efficient FD discovery algorithm when applied to datasets with many rows (> 100,000 rows) and few columns (< 14 columns). This puts it in a special position to rule mine clinical and demographic datasets, which often consist of long and narrow sets of participant records. The structure of FD_Mine is described and supplemented with a formal proof of the equivalence pruning method used. FDTool is a re-implementation of FD_Mine with additional features added to improve performance and automate typical processes in database architecture. The experimental results of applying FDTool to 13 datasets of different dimensions are summarized in terms of the number of FDs checked, the number of FDs found, and the time it takes for the code to terminate. We find that the number of attributes in a dataset has a much greater effect on the runtime and memory costs of FDTool than does row count. The last section explains in detail how the FDTool application can be accessed, executed, and further developed.

Keywords

Functional dependencies, Data mining, Electronic health records, Relational database, FDTool, Rule discovery

This article is included in the Python collection.

**Amendments from Version 1**

In response to the reviewers’ comments, in this revision we corrected grammatical and typographical errors.

In the abstract, we clarify that the experimental comparison of several functional dependency algorithms is referenced from previous research.

In the sentence following Definition 6, we substituted the phrase “determines equivalent attributes sets with” with “determines equivalent attribute sets using”, since the FDTool code uses the functional dependencies discovered at each level to generate equivalent attribute sets.

We uploaded publicly available data with the same shape and structure as the 13 CARES datasets. We base all simulation studies on the publicly available data, which can be found in FDTool/data/input/CARES/ as part of the FDTool repository and archived our Zenodo project.

See referee reports.

---

**Introduction**

Functional dependencies (FDs) are key to understanding how attributes in a database schema relate to one another. An FD defines a rule constraint between two sets of attributes in a relation \( r(U) \), where \( U = \{v_1, v_2, \ldots, v_n\} \) is a finite set of attributes (Yao et al., 2002). A combination of attributes over a dataset is called a candidate (Yao & Hamilton, 2008-). A combination of attributes over a dataset is called a candidate. There remain 2\(^{n+1} - 2\) = 2\(^{n+1} - 2\) = 14 nonempty subsets of \( U \) that are to be considered candidates.

Power set lattice

The search space for FDs can be represented as a *power set lattice* of nonempty attribute combinations. Figure 1 gives the nonempty attribute combinations of a relation \( r(U) \) such that \( U = \{A, B, C, D\} \). There are \( 2^n - 1 = 2^4 - 1 = 15 \) attribute subsets in the power set lattice (Yao & Hamilton, 2008). Each combination \( X \) of the attributes in \( U \) can be the left-hand side of an FD \( X \rightarrow Y \) such that \( X \rightarrow Y \) is satisfied by relation \( r(U) \) (Yao & Hamilton, 2008). Since the attribute set itself \( U \) trivially determines each one of its proper subsets, it can be ignored as a candidate. There remain \( 2^n - 2 = 2^4 - 2 = 14 \) nonempty subsets of \( U \) that are to be considered candidates.

There are \( n \cdot 2^n - 2 = n \cdot 2^4 - 2 = 28 \) edges (or arrows) in the semi-lattice of the complete search space for FDs in relation \( r(U) \) (Yao & Hamilton, 2008). The size of the search space for FDs is exponentially related to the number of attributes in \( U \). Hence, the search space for FDs increases quite significantly when there is

---

\(^1\)Each attribute \( v_i \) has a finite domain, written \( \text{dom}(v_i) \), representing the values that \( v_i \) can take on. For a subset \( X = \{v_1, \ldots, v_m\} \) of \( U \), we write \( \text{dom}(X) \) for the Cartesian product of the domains of the individual attributes in \( X \), namely, \( \text{dom}(X) = \text{dom}(v_1) \times \ldots \times \text{dom}(v_m) \) (Yao & Hamilton, 2008). A relation \( r \) on \( U \), denoted \( r(U) \), is a finite set of mappings \( \{t_1, \ldots, t_m\} \) from \( U \) to \( \text{dom}(U) \) with the restriction that for each mapping \( t \in r(U) \), \( t(v) \) must be in \( \text{dom}(v) \), \( 1 \leq i \leq m \), where \( t(v) \) denotes the value obtained by restricting the mapping \( t \) to \( v \). Each mapping \( t \) is called a *tuple* and \( t(v) \) is called the \( v \)-value of \( t \) (Maier, 1983).

---

![Figure 1. Nonempty combinations of attributes A, B, C, and D by k-level.](image-url)
a greater number of attributes in $U$. For instance, when there are 12 attributes in a relation, the search space for FDs climbs to 24,564. This gives reason to be cautious of runtime and memory costs when deploying a rule mining algorithm to discover FDs.

**Partition**

The algorithms used to discover FDs differ in their approach to navigating the complete search space of a relation. Their candidate pruning methods vary and sometimes the methods used to validate FDs do as well. These differences affect runtime and memory behavior when used to process tables of different dimensions.

A common data structure used to validate FDs is the partition. A partition places tuples that have the same values on an attribute into the same group (Yao et al., 2002).

**Definition 2.** Let $X \subseteq U$ and let $t_1, \ldots, t_n$ be all the tuples in a relation $r(U)$. The partition over $X$, denoted $\Pi_X$, is a set of the groups such that $t_i$ and $t_j$, $1 \leq i, j \leq n$, $i \neq j$, are in the same group if and only if $t_i[X] = t_j[X]$ (Yao et al., 2002).

It follows from Definition 2 that the cardinality of the partition $\text{card}(\Pi_X(r))$ is the number of groups in partition $\Pi_X$ (Yao & Hamilton, 2008). The cardinality of the partition offers a quick approach to validating FDs in a dataset.

**Theorem 1.** An FD $X \rightarrow Y$ is satisfied by a relation $r(U)$ if and only if $\text{card}(\Pi_X) = \text{card}(\Pi_{XY})$ (Huhtala et al., 1999).

Theorem 1 provides an efficient method to check whether an FD $X \rightarrow Y$ holds in a relation. Huhtala et al. (1999) proved it to support a fast validation method for relations consisting of a large number of tuples.

**Closure**

Efforts in relational database theory have led to more runtime and memory efficient methods to check the complete search space of a relation for FDs. In place of needing each arrow in a semi-lattice checked, we can infer the FDs that logically follow from those already discovered. Such FDs are to be discovered as a consequence of Armstrong’s Axioms (Maier, 1983) and the inference axioms derivable from them (Ramakrishnan & Gehrke, 2000), which are

- **Reflexivity:** $Y \subseteq X$ implies $X \rightarrow Y$;
- **Augmentation:** $X \rightarrow Y$ implies $XZ \rightarrow YZ$;
- **Transitivity:** $X \rightarrow Y$ and $Y \rightarrow Z$ imply $X \rightarrow Z$;
- **Union:** $X \rightarrow Y$ and $X \rightarrow Z$ imply $X \rightarrow YZ$;
- **Decomposition:** $X \rightarrow YZ$ implies that $X \rightarrow Y$ and $X \rightarrow Z$.

These axioms signal the distinction between FDs that can be inferred from already discovered FDs and those that cannot (Maier, 1983). Exploiting what can be derived from Armstrong’s Axioms allows us to avoid having to check many of the candidates in a search space.

**Definition 3.** Let $F$ be a set of functional dependencies over a dataset $D$ and $X$ be a candidate over $D$. The **closure of candidate $X$ with respect to $F$**, denoted $X^*$, is defined as $\{ Y \mid X \rightarrow Y \text{ can be deduced from } F \text{ by Armstrong’s Axioms} \}$ (Yao & Hamilton, 2008).

The **nontrivial closure** of candidate $X$ with respect to $F$ is defined as $X^* = X^* \setminus X$ and written $X^* \text{ (Yao & Hamilton, 2008). Definition 3 gives room to elegantly define keys. Informally, a key implies that a relation does not have two distinct tuples with the same values on those attributes. Keys uniquely identify all tuple records in a dataset.}
**Definition 4.** Let $R$ be a relational schema and $X$ be a candidate of $R$ over a dataset $D$. If $X \cup X^* = R$, then $X$ is a key (Yao et al., 2002).

A candidate key $X$ of a relation is a minimal key for that relation. This means that there is no proper subset of $X$ for which Definition 4 holds.

**Rule mining algorithms**

Existing functional dependency algorithms are split between three categories: Difference- and agree-set algorithms (e.g., Dep-Miner, FastFDs), Dependency induction algorithms (e.g., FDEP), and Lattice traversal algorithms (e.g., TANE, FUN, FD_Mine, DFD) (Papenbrock et al., 2015).

**Difference- and agree-set algorithms** model the search space of a relation as the cross product of all tuple records (Papenbrock et al., 2015). They search for sets of attributes agreeing on the values of certain tuple pairs. Attribute sets only functionally determine other attribute sets whose tuple pairs agree, i.e., agree-sets (Asghar & Ghenai, 2015; Papenbrock et al., 2015). Then, agree-sets are used to derive all minimal FDs.

**Dependency induction algorithms** assume a base set of FDs in which each attribute functionally determines each other attribute (Papenbrock et al., 2015). While iterating through row data, observations are made that require certain FDs to be removed from the base set and others added to it. These observations are made by comparing tuple pairs based on the equality of their projections. After each record in a dataset is compared, the FDs left in the base set are considered valid, minimal and complete (Papenbrock et al., 2015).

**Lattice traversal algorithms** model the search space of a relation as a power set lattice. Most of such algorithms, (i.e., TANE, FUN, FD_Mine) use a level-wise approach to traversing the search space of a relation from the bottom-up (Papenbrock et al., 2015). They start by checking for FDs that are singleton sets on the left-hand side and iteratively transition to candidates of greater cardinality.

**Performance**

Papenbrock et al. (2015) released an experimental comparison of the aforementioned FD discovery algorithms. The seven algorithms were re-implemented in Java based on their original publications and applied to 17 datasets of various dimensions. They found that none of the algorithms are suited to yield the complete result set of FDs from a dataset consisting of 100 columns and 1 million rows (Papenbrock et al., 2015). Hence, it is a matter of discretion to choose the algorithm best fitting the dimensions of a dataset.

The experimental results show that lattice traversal algorithms are the least memory efficient, since each $k$-level can be a factor greater than the size of the previous level (Papenbrock et al., 2015). Difference- and agree-set algorithms and dependency induction algorithms perform favorably in memory experiments as a result of their operating directly on data and efficiently storing result sets. Lattice traversal algorithms scale poorly on tables with many columns (≥ 14 columns) due to memory limits (Papenbrock et al., 2015).

Lattice traversal algorithms are the most effective on datasets with many rows, because their validation method operates on attribute sets as opposed to data (Papenbrock et al., 2015). This puts such algorithms in a special position to rule mine clinical and demographic record datasets, which often consist of long and narrow sets of participant records. Difference- and agree-set algorithms and dependency induction algorithms commonly reach time limits when applied to datasets of these dimensions (> 100,000 rows) (Papenbrock et al., 2015).

**Lattice traversal algorithms**

Lattice traversal algorithms iterate through $k$-levels represented in a power set lattice. If the lattice is traversed from the bottom-up, we say the algorithm is level-wise.

**Definition 5.** Let $X_1, X_2, \ldots, X_k, X_{k+1}$ be $(k + 1)$ attributes over a database $D$. If $X_1X_2\ldots X_k \rightarrow X_{k+1}$ is an FD with $k$ attributes on its left hand side, then it is called a $k$-level FD (Yao et al., 2002).

---

1We say that an FD is checked when Theorem 1 is used to see if it holds or not (Yao et al., 2002).
2Definition 5.
3Theorem 1.
The search space for FDs is reduced at the end of each iteration using pruning rules. Pruning rules check the validity of candidates not yet checked with FDs already discovered and those inferred from Armstrong’s Axioms (Yao & Hamilton, 2008). After a search space is pruned, an Apriori_Gen principle generates \( k \)-level candidates with the \((k-1)\)-level candidates that were not pruned (Yao & Hamilton, 2008).

**Apriori_Gen:**
- **oneUp:** generates all possible candidates in \( C_k \) from those in \( C_{k-1} \).
- **oneDown:** generates all possible candidates in \( C_{k-1} \) from those in \( C_k \).

Level-wise lattice traversal algorithms stop iterating after all candidates in a search space are pruned. In this case, Apriori_Gen generates the null set \( \emptyset \) raising a flag for the algorithm to terminate. This has the effect of shortening runtime to the degree that FDs are discovered and others are inferred.

**Tane**
The level-wise lattice traversal algorithms TANE, FUN, and FD_Mine differ in terms of pruning rules. FUN and FD_Mine expand on the pruning rules of TANE. Released by Huhtala et al. (1999), TANE prunes a search space on the basis that only minimal and non-trivial\(^7\) FDs need be checked. TANE restricts the right-hand side candidates \( C^+ \) for each attribute combination \( X \) to the set

\[
C^+(X) = \{ A \in R \mid \forall B \in X : \{A,B\} \rightarrow B \text{ does not hold} \},
\]

which contains all the attributes that the set \( X \) may still functionally determine (Papenbrock et al., 2015). The set \( C^+ \) is used in the following pruning rules (Papenbrock et al., 2015).

- **Minimality pruning:** If an FD \( X \not\rightarrow A \) holds, \( A \) and all \( B \in C^+(X) \setminus X \) can be removed from \( C^+(X) \).
- **Right-hand side pruning:** If \( C^+(X) = \emptyset \), the attribute combination \( X \) can be pruned from the lattice, as there are no more right-hand side candidates for a minimal FD.
- **Key pruning:** If the attribute combination \( X \) is a key, it can be pruned from the lattice. Key pruning implies that all supersets of a key, i.e., super keys, can be removed, since they are by definition non-minimal (Huhtala et al., 1999).

**FD_Mine**
Like TANE and FUN, FD_Mine is structured around the level-wise lattice traversal approach and the aforementioned pruning rules. Unlike the other two algorithms, FD_Mine, authored by Yao et al. (2002), uses the concept of equivalence as means to more exhaustively prune the search space of a candidate (Papenbrock et al., 2015). Informally, attribute sets are equivalent if and only if they are functionally dependent on each other (Papenbrock et al., 2015).

The proofs demonstrating that no useful information is lost in pruning candidates from equivalent attribute sets are reproduced in this section and were originally developed by Yao & Hamilton (2008). The equivalence pruning method can be derived directly from Armstrong’s Axioms.

**Definition 6.** Let \( X \) and \( Y \) be candidates over a dataset \( D \). If \( X \rightarrow Y \) and \( Y \rightarrow X \) hold, then we say that \( X \) and \( Y \) are an equivalence and denote it as \( X \leftrightarrow Y \).

After a \( k \)-level is fully validated, i.e., each \( k \)-level candidate is checked, FD_Mine determines equivalent attribute sets using the FDs already discovered.

**Theorem 2.** Let \( X, Y \subseteq U \). If \( Y \subseteq X^* \) and \( X \subseteq Y^* \), then \( X \leftrightarrow Y \) (Yao & Hamilton, 2008).

**Proof.** Since \( X \rightarrow X^* \) and \( Y \subseteq X^* \), Decomposition implies that \( X \rightarrow Y \). By a similar argument, \( Y \rightarrow X \) holds. Because \( X \rightarrow Y \) and \( Y \rightarrow X \), we have by definition that \( X \leftrightarrow Y \) holds.

\(^7\) An FD \( X \rightarrow A \) is non-trivial if and only if \( X \not\in A \) (Huhtala et al., 1999).
Lemma 3 and Lemma 4 are derived from Armstrong’s Axioms with the assumption of the equivalence \( X \leftrightarrow Y \).

**Lemma 3.** Let \( W, X, Y, Z \subseteq U \) and \( Y \subseteq Y' \). If \( X \leftrightarrow Y \) and \( XW \rightarrow Z \), then \( Y'W \rightarrow Z \) (Yao & Hamilton, 2008).

**Proof.** Suppose that \( X \leftrightarrow Y \) and \( XW \rightarrow Z \). This implies that \( X \rightarrow Y \). By Augmentation, \( YW \rightarrow XW \). By Transitivity, \( YW \rightarrow XW \) and \( XW \rightarrow Z \) give that \( YW \rightarrow Z \). By Augmentation, \( Y \setminus Y \) can be added to both sides of \( YW \rightarrow Z \) to give that \( YW(Y' \setminus Y) \rightarrow Z(Y' \setminus Y) \). By \( Y \subseteq Y' \), we know that \( YW \rightarrow Z(Y \setminus Y) \). Then, by Decomposition, \( Y'W \rightarrow Z \).

**Lemma 4.** Let \( W, X, Y, Z \subseteq U \). If \( X \leftrightarrow Y \) and \( WZ \rightarrow Y \), then \( WZ \rightarrow Y' \) (Yao & Hamilton, 2008).

**Proof.** By \( X \leftrightarrow Y \), we know that \( X \rightarrow Y \). By Transitivity, \( WZ \rightarrow X \) and \( X \rightarrow Y \) imply \( WZ \rightarrow Y \).

Theorem 2 checks attribute sets \( X \) and \( Y \) for the equivalence \( X \leftrightarrow Y \). FD_Mine assumes that the attribute set \( Y \) is generated before \( X \). By Lemma 3 and Lemma 4, we know that for equivalence \( X \leftrightarrow Y \), no further attribute sets \( Z \) such that \( Y \subseteq Z \) need be checked (Yao & Hamilton, 2008). Hence, \( Y \) is deleted as a result of the following pruning rule.

- **Equivalence pruning:** If \( X \leftrightarrow Y \) is satisfied by relation \( r(U) \), then candidate \( Y \) can be deleted. (Yao & Hamilton, 2008).

Exploiting the equivalence pruning method leaves FD_Mine in a more aggressive position to prune candidates than TANE. This offers an advantage in terms of runtime and memory behavior (Yao et al., 2002).

**Non-minimal FDs**

The pseudo-code proposed in the second version of FD_Mine (Yao & Hamilton, 2008) will under certain circumstances output non-minimal FDs (Papenbrock et al., 2015). FD_Mine references an Apriori Gen method (Agrawal et al., 1996) stating that for each pair of candidates \( p, q \in C_i \), the set \( p \cup q \) is to be placed in \( C_{i+1} \) if \( \text{card}(p \cup q) = k \). Example 1 shows that the Apriori Gen method referenced and utilized by FD_Mine can violate minimality pruning by checking supersets that need not be checked. Figure 2 gives the power set lattice of the relation described in Example 1 pruned by FD_Mine.

**Example 1.** Let \( r(U) \) be a relation such that \( U = \{A, B, C, D, E\} \). Suppose that \( AB \) is a key and that there are no other FDs in \( r(U) \). Since \( AB \) is a key, we know by definition that \( AB \cup AB^* = U \). Provided this and that there are no other FDs in \( r(U) \), the candidates \( ABC, ABD \) and \( ABE \) are deleted from \( C_i \), and so \( C_i = \text{Prune}(\text{Apriori Gen}(C_i)) = \{ACE, BCE, ACD, BCD, ADE, CDE, BDE\}^1 \). Then, \( C_i = \{ACD, ABC, ACDE, ABDE, BCDE\} \).

---

\(^1\) Since \( E = \emptyset \) in this example, we can ignore the argument \( E \) in the function \( \text{Prune()} \). For simplicity’s sake, we ignore the argument \( \text{Closure} \).

---

**Figure 2. A pruned power set lattice.** FD_Mine deletes the candidates \( ABC, ABE, \) and \( ABD \) (red ovals) as a result of finding the candidate key \( AB \) (blue hexagon). It generates supersets of \( AB \) (yellow rectangles) at the next level.
it must be that $AB^* = \{C, D, E\}$, the algorithm validates the FDs $ABCD \rightarrow E$, $ABCE \rightarrow D$, and $ABDE \rightarrow C$. Since $E$, for example, is functionally dependent on the proper subset $AB \subseteq ABCD$, $ABCD \rightarrow E$ is non-minimal.

The Apriori Gen principle presented in TANE (Huhtala et al., 1999) more effectively generates candidate level $C_{k+1}$ from $C_k$. It requires that $C_{k+1}$ only contains the attribute sets of size $k + 1$ which have all their subsets of size $k$ in $C_k$ (Huhtala et al., 1999); i.e.,

$$C_{k+1} = \{X | \text{card}(X) = k + 1 \text{ and for all } Y \text{ with } Y \subseteq X \text{ and } \text{card}(Y) = k \text{ we have } Y \in C_k\}.$$ 

In reference to Example 1, this method does not insert the candidate $ABCD$ in $C_k$, without loss of generality, because $ABC \subseteq ABCD$ but $ABC \notin C_k$. Thus, the non-minimal FD $ABCD \rightarrow E$ is not checked.

**Prune**($C_k, E, \text{Closure})$\(^{10,11}\)

01 for each $S \in C_k$;
02 for each $X \in \text{oneDown}[C_k]$;
03 \hspace{1em} if ($X \subseteq S$) then:
04 \hspace{2em} if ($X \in \{Z | Y \rightarrow Z \in E\}$) then: \# Pruning rule 1
05 \hspace{2em} delete $S$ from $C_k$
06 \hspace{2em} if $S \subseteq X^+$ then: \# Pruning rule 2
07 \hspace{2em} delete $S$ from $C_k$
08 \hspace{2em} $S^+ = S^+ \cup X^+$ \# Pruning rule 3
09 \hspace{2em} if $U == S^+$ then: \# Pruning rule 4
10 \hspace{2em} delete $S$ from $C_k$
11 return $C_k, \text{Closure},$

FD_Mine will under the circumstance described in Example 1 set closure values incorrectly. In line 2, FD_Mine iterates through $C_{k-1}$, as opposed to oneDown [$C_k$], which can cause the Prune() function to ignore setting the closure values of certain candidates. In Example 1, FD_Mine does not accurately set the closure $ABCD^*$ to $E$, since $E$ is not saved to the closure values of the candidates $ACD, BCD \subseteq ABCD$ at the previous level. Iterating through oneDown [$C_k$] sets the closure of a candidate to the union of the closure values of its proper subsets, so that the closure values of deleted candidates are not lost among their supersets.

Properly assigned closure values can allow the algorithm to avoid checking many non-minimal FDs. This is because the ObtainFDs module, i.e., the validation method, only checks\(^{12}\) the right-hand side attributes $v_i$ for which $v_i \in U \setminus X^*$ (Yao & Hamilton, 2008). Hence, provided that Pruning rule 3 asserts the equality $ABCD^* = E$, $ABCD \rightarrow E$ need not be checked.

**Operation**

FDTool (Buranosky, 2018) is a command line Python application executed with the following statement: $fdtool /path/to/file$\(^{13}\). For Windows users, this is to be run from the working directory of fdtool.exe, which will likely be $C:\Python27\Scripts$ for those installing with pip install fdtool. For other systems, installation automatically inserts the file path to the fdtool command in the PATH variable. /path/to/file is the absolute or relative path to a .txt, .csv, or .pkl file containing a tabular dataset. If the data file has the extension .txt or .csv, FDTool detects the following separators: comma (‘,’), bar (‘|’), semicolon (‘;’), colon (‘:’), and tilde (‘~’). The data is read in as a Pandas data frame\(^{14}\).

---

\(^{9}\)Closure = $\{X^* | X \in C_k \vee X \in \text{oneDown}[C_k]\}$.

\(^{10}\)Equivalent candidates are stored in $E$.

\(^{11}\)All candidates at level $k$ are stored in $C_k$.

\(^{12}\)Assume the left-hand side attribute set $X$.

\(^{13}\)Edit FDTool/fdtool/config.py prior to building setup with python setup.py install to change preset time limit or max $k$-level.

\(^{14}\)The data is read in with the Pandas function read_csv(), which is subject to the usual spacing errors associated with reading in delimiter-separated values.
Dependencies:

1. Python2 (https://www.python.org), recommended version 2.7.8 or later.

FDTool provides the user with the minimal FDs, equivalent attribute sets and candidate keys mined from a dataset. This is given with the time (s) it takes for the code to terminate (after reading in data), the row count and attribute count of the data, the number of FDs and equivalent attribute sets found, and the number of FDs checked. This is printed on the terminal after the code is executed as shown in Figure 3. The information is saved to a .FD_Info.txt file.

Figure 3 shows the printed output of FDTool.exe applied to the contents of Table 1. The output file Table1.FD_Info.txt is saved to the user’s current working directory.

Implementation

FDTool is a Python based re-implementation of the FD_Mine algorithm with additional features added to automate typical processes in database architecture. FD_Mine was published in two papers with more detail given to the scientific concepts used in algorithms of its kind (Yao et al., 2002; Yao & Hamilton, 2008). The two

versions of FD_Mine were released with different structures but make use of the same theoretical foundation
(Papenbrock et al., 2015), which is fully supported in mathematical proofs of the pruning rules used (Yao &
Hamilton, 2008). FDTool was coded\textsuperscript{15} with special attention given to the pseudo-code presented in the second
version of FD_Mine (Yao & Hamilton, 2008).

The Python script \texttt{dbschema.py} in FDTool/fdtool/modules/dbschema is taken from \texttt{dbschemacmd}
on functional dependencies (Elmasri & Navathe, 2011). It is used to take sets of FDs and infer candidate
keys from them. The operation first assigns the left-hand side attribute combinations of a set of FDs to dictionary
keys and their closures to the corresponding values. It then reduces the set of FDs to a minimum coverage\textsuperscript{16}. Candidate keys are assembled using the minimum coverage and closure structure by adding attributes to key
candidates until each minimal attribute set X for which $X^* = U$ is found. Details on the dbschema operations are
described in FDTool/fdtool/modules/dbschema/Docs.

**Use cases**

FDTool was initially created to help decompose datasets of medical records as part of Clinical Archived
Records research for Environmental Studies (CARES). CARES currently contains 13 datasets obtained from
the medical software firms Epic and Legacy. The attribute count in this database ranges from 4 to 18; the row
count ranges from 42,369 to 8,201,636.

**Experimental results**

To limit the strain on computational resources, FDTool has a built in time limit of 4 hours. FDTool reaches
this preset limit (triggering program termination) when applied to the PatientDemographics dataset (42,369
rows × 18 columns) and the EpicVitals_TobaccoAlcOnly dataset (896,962 rows × 18 columns). The
remaining 11 CARES datasets are given in Table 2\textsuperscript{17}.

**Experimental summary**

The results from Table 2 show that runtime is primarily determined by the number of attributes in a dataset. For
instance, the LegacyPayors dataset (1,465,233 rows × 4 columns) has slightly more rows (13% increase) but
far fewer attributes (60% decrease) as compared to the AllLabs dataset (1,294,106 rows × 10 columns). The
runtime of LegacyPayors (9.4 s.) is much less than that of AllLabs (999.8 s.), because AllLabs has many more
arrows in its powerset lattice,

$$n \cdot 2^{n-1} - n = 10 \cdot 2^{9.1} - 10 = 5110,$$

than does LegacyPayors (28). Hence, FDTool has more FDs to check when applied to AllLabs. It is clear
that the attribute count of a dataset has a much greater effect on the runtime of FDTool than does row count.

Many of the arrows in the powerset lattice of a candidate are pruned by FDTool. AllLabs has 5,110 arrows in its
powerset lattice. However, FDTool only checks 818 FDs, as there are many inferred from the 43 FDs found. This
follows from the \texttt{Prune()} function, which deletes many of the candidates to check partially as a result of mining
4 equivalent attribute sets. FDTool terminates after 5 $k$-levels when applied to AllLabs.

**Future development**

We want to improve its performance so that FDTool is better equipped to handle datasets of different dimen-
sions. Using the dependency induction algorithm FDEP, the reach of FDTool could be extended to datasets
with fewer rows and more than 100 columns (Papenbrock et al., 2015). This might also require upgrading the
source code with multicore processing methods, such as a Java API, to reduce runtime and avoid reaching
memory limits. A formal proof of the dbschema operations is also desired.

\textsuperscript{15}FDTool was tested regularly throughout the implementation process so as to accommodate to changes made to improve
runtime and memory behavior.

\textsuperscript{16}A set of FDs $F$ is a coverage of another set of FDs $G$ if every FD in $G$ can be inferred from $F$; i.e., $G^u \subseteq F^u$ (Soule, 2014).

A set of FDs $F$ is a minimum coverage of $G$ if $F$ is the smallest set of FDs that covers $G$ (Soule, 2014).

\textsuperscript{17}OS: Windows 10; Installed memory (RAM): 256 GB; Processor: Intel Core, 1 CPU; Clock speed: 2.19 GHz; Python: 2.7.12; Pandas:
0.18.1.
Another goal is to increase the functionality provided by FDTool. This would mean implementing the pen and paper methods typically used to normalize relational schema and decompose tables. Our intent is to incorporate these changes in newer versions of FDTool, released at regular periods, so as to develop it as Python software that could automate much of what is done in the database design process.

Data availability

While the authors fully support the open dissemination of data for verification and replication purposes, CARES data cannot be released as it contains Protected Health Information. For the purpose of testing the runtime and memory behavior of FDTool, we have produced simulated copies of all 13 datasets in the CARES collection. These datasets are publicly available in FDTool/data/input/CARES as part of the FDTool repository and archived in the above Zenodo project.

Data are available under the terms of the Creative Commons Attribution 4.0 International license (CC-BY 4.0).

Software availability
FDTool is available from the Python Package Index: https://pypi.org/project/fdtool/

Latest source code: https://github.com/USEPA/FDTool.git

Source code at time of publication: https://doi.org/10.5281/zenodo.1442842

License: CC0 1.0 Universal. Module FDTool/fdtool/modules/dbschema released under a modified C-FSL license.

Author contributions
MB and ES designed and implemented the software. MB wrote the manuscript. CWC supervised MB, and reviewed the manuscript. EP maintained the research data. DDS coordinated the funding for the project. All authors agreed to the final content of the manuscript.

Grant information
This work was funded by the US Environmental Protection Agency. The work presented here does not necessarily reflect the views or policy of the EPA. Any mention of trade names does not constitute endorsement by the EPA.

The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

This paper outlines in detail FDTool: a Python application to mine for functional dependencies. The paper is about developing a database tool that improves FD Mine a previous tool for functional dependencies.

The definitions, problem statement and explanations in this paper are well written and clear. The authors also provide a good comparison of several functional dependence discovery algorithms.

In my opinion, it would be nice to have the experimental results and summary in some more detail. Also since the CARES data is not public it would be nice to have some results on available data.

Is the rationale for developing the new software tool clearly explained?
Yes

Is the description of the software tool technically sound?
Yes

Are sufficient details of the code, methods and analysis (if applicable) provided to allow replication of the software development and its use by others?
Partly

Is sufficient information provided to allow interpretation of the expected output datasets and any results generated using the tool?
Yes

Are the conclusions about the tool and its performance adequately supported by the findings presented in the article?
Yes

Competing Interests: No competing interests were disclosed.
Reviewer Expertise: Statistical and computation methods.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

The article is well-structured and well-written. It contains nice presentations of appropriate definitions, theorems, algorithms, examples, and use-cases.

The article has clear contributions:

In the theory part: It enhances the FD_Mine algorithm by improving performance and automating typical processes.

In the implementation part: The authors re-implement the FD_Mine algorithm, which is otherwise not publicly available as a software tool.

In the experiment part: The authors apply FDTool to 12 datasets of different dimensions.

Findings: The effect of the attributes is greater than the records on the runtime and memory costs of the FDTool.

Additional contributions:

The article clearly describes the features of the FDTool, such as its usage and execution. It also depicts future research opportunities with respect to the further development of the FDTool.

Major Comment:

In the abstract, it says, “We conclude that FD_Mine is the most efficient FD discovery algorithm when applied to datasets with many rows (> 100,000 rows) and few columns (< 14 columns).” The word “conclude” does not seem appropriate here. If this result indeed follows from your research, please explain how the results shown in Table 2 support this claim with respect to all datasets shown in the table [This explanation could be added in the experimental results or experimental summary section]. However, if the conclusion is in fact being taken from Papenbrock, then wording might be adjusted to “Previous research established that FD_Mine ….” You may want to state your conclusions about your software tool.
Minor corrections:

Please use either "FD_Mine" or "FD Mine" everywhere. The original paper had FD_Mine.

Please use same format (comma or no comma) for large numbers [e.g. “the row count ranges from 42,369 to 8,201,636” in the use cases section versus “AllLabs dataset (1294106) and “AllLabs has 5110 arrows in its powerset lattice” in the experimental summary]. Also please check the experimental results section.

In Definition 2, please correct “i 1≠ j”, presumably to “i ≠ j”.

In the text immediately after Definition 6, please change “determines equivalent attribute sets with” to “determines attribute sets equivalent to”.

In the first line of the closure section, please change “lead” to “led”.

In the future development section, please remove the extra “the” from “A formal proof of the the dbschema operations is also desired”.

Table 1 has no title. Please give a title for Table 1.

Table 2 shows 11 datasets but the table title [and the description in the experimental results section] mentions 10 datasets. Could you please correct this inconsistency.

Is the rationale for developing the new software tool clearly explained?
Yes

Is the description of the software tool technically sound?
Yes

Are sufficient details of the code, methods and analysis (if applicable) provided to allow replication of the software development and its use by others?
Yes

Is sufficient information provided to allow interpretation of the expected output datasets and any results generated using the tool?
Yes

Are the conclusions about the tool and its performance adequately supported by the findings presented in the article?
Partly

We confirm that we have read this submission and believe that we have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

The benefits of publishing with F1000Research:

- Your article is published within days, with no editorial bias
- You can publish traditional articles, null/negative results, case reports, data notes and more
- The peer review process is transparent and collaborative
- Your article is indexed in PubMed after passing peer review
- Dedicated customer support at every stage

For pre-submission enquiries, contact research@f1000.com
