SYSTEMATIC REVIEW

The effects of interventions preventing self-harm and suicide in children and adolescents: an overview of systematic reviews [version 2; peer review: 2 approved]

Abstract

Background: Self-harm and suicide in children and adolescents are of serious consequence and increase during the adolescent years. Consequently, there is need for interventions that prevent such behaviour. The objective of this paper: to evaluate the effects of interventions preventing self-harm and suicide in children and adolescents in an overview of systematic reviews.

Methods: We conducted an overview of systematic reviews (OoO). We included reviews evaluating any preventive or therapeutic intervention. The methodological quality of the included reviews was assessed independently, and data was extracted by two reviewers. We report the review findings descriptively. The certainty of evidence was assessed using Grading of Recommendations Assessment, Development and Evaluation (GRADE).

Results: Moderate certainty evidence suggests that school-based interventions prevent suicidal ideation and attempts short term, and possibly suicide attempts long term. The effects of community-based interventions following suicide clusters and local suicide plans are unknown, as are the benefits and harms of screening young people for suicide risk.

The effects of most interventions targeting children and adolescents with known self-harm are unknown. However, low certainty evidence suggests that dialectical behavioural therapy and developmental group therapy are equally as effective on repetition of self-harm as enhanced treatment as usual.

Conclusions: Research on several recommended practices, such as local suicide plans, prevention of suicide clusters and approaches to risk assessment, is lacking. When such interventions are implemented, the effects should be closely evaluated. There is also need for more research on treatment of repeated self-harm. Further research should include long term follow-up, and investigate possible adverse effects.

In prevention of self-harm and suicide in children and adolescents, policy makers and health providers should consider evidence from population-based studies with mixed-age samples, adult samples, and studies on conditions associated with self-harm and/or suicidality, such as...
depression and psychosis.

Introduction

Self-harm involves intentional self-poisoning or self-injury, irrespective of type of motive or the intent of suicidal intent\(^1\). It is often a coping mechanism used to solve a difficult situation, and can serve functions such as affect regulation, communicating the extent of pain, or self-punishment\(^2\). While self-harm is rare in children younger than 12 years\(^3\), it is prevalent amongst adolescents\(^4\), across international studies, 18% between the ages of 12 and 18 report a history of one or several episodes of intentional self-harm. Prevalence is highest amongst adolescent girls, typically done by cutting, but self-harm is also a problem amongst boys, more often hitting themselves\(^5\). It may be temporary or more long-lasting in nature\(^6\), and one episode of self-harm is a strong predictor of repetition\(^7\). When repeated, the person often advances to a combination of different methods, increasing the medical severity\(^8\). Completed suicide is on the other hand defined as the act of intentionally ending one’s own life\(^9\). Suicide is rare before the age of 15 but increases in prevalence through adolescence\(^0\), and is somewhat most prevalent amongst males\(^1\). It is the most common cause of death in female adolescents, and the third most common cause of death in male adolescents (after road-traffic accidents and violence)\(^1\). Self-harm and suicide result from underlying risk- and maintaining factors, spanning from other mental health problems such as depression, biological factors, exposure to traumatic events or other difficult circumstances in the young person’s environment\(^1\). Furthermore, there are repercussions to being exposed to family and/or friends’ self-harm and suicide. Such exposure may contribute to self-harm and suicide in adolescents, a phenomenon referred to as “social contagion”\(^2\). Related, the bereavement process of survivors after losing a significant other may last a long time and increase the risk of suicide\(^3\) and suicidal thoughts\(^4\).

Evidently, self-harm and suicide in children and adolescents are complex and multifaceted phenomena. As prevention likely warrants a variation of measures, clinicians and policy makers are in need of knowledge the effects of different types of preventive interventions.

There are several reviews with summarized evidence on effects of interventions aimed at preventing (re)occurrence of self-harm and suicide. However, many reviews are of variable quality, or outdated\(^5\). Furthermore, there is a large overlap of interventions covered in the different reviews, making it difficult for professionals to sort out the best available evidence needed to make informed decisions\(^6\). Consequently, we wanted to provide an up-to-date overview of the best quality summarized evidence on effects of all types of interventions aimed at preventing self-harm and suicide.

Objective

The objective of this review is to summarize the effects of interventions aimed at preventing self-harm and suicide in children and adolescents.

Methods

This review was registered with the international prospective register of systematic reviews (PROSPERO; CRD42019117942) on February 8, 2019.

Inclusion and exclusion criteria

We included systematic reviews published in 2012 and later (last date searched August 2018), and fulfilling the DARE-criteria\(^7\). This five-year cut-off is pragmatic in considering that older reviews are no longer a reliable basis for updated evidence. A review published earlier than 2012 may not include primary studies published the last >10 years. Furthermore, to include the broadest possible evidence base, we included reviews in all the languages available to us: English, Norwegian, Danish or Swedish. The other inclusion criteria (PICO) are presented in Box 1.

Amendments from Version 1

We wish to thank the reviewers for valuable comments on the manuscript. The main differences compared with the previous version are:

- We describe the reason for the five-year cut-off in our search for systematic reviews. This cut-off is pragmatic but similarly practiced by others, e.g. the Cochrane Library (https://community.cochrane.org/editorial-and-publishing-policy-resource/cochrane-review-development/cochrane-review-updates), in considering that older reviews are in need of being updated. It takes time before a review is published, and it may be published one to three years after the search for primary studies. Thus, a review published earlier than 2012 may not include primary studies published the last >10 years. This has improved with time and new publication standards for reviews.
- We have made it explicit that the search-words are included in the IN SUM Search Strategy (extended data, reference\(^2\)) and that we screened providing all the references in IN SUM. We also provide examples of search words. IN SUM is a database of systematic reviews on effects of child mental health and welfare interventions from the following databases: Cochrane Database of Systematic Reviews, Campbell Library, PsycINFO, MEDLINE, Embase, Web of Science, Database of Abstracts of Reviews of Effects (DARE) and Evidence Based Mental Health.
- We have tried to make the introduction and discussion more coherent and on point about the main message, and we comment the implications of TAU versus other active intervention control groups.
- We have added information on the importance of biological factors and bereavement as risk factors in the introduction and the summary.
- We have added information about why including reviews in English, Norwegian, Danish or Swedish: we have included languages available to us, and guidelines developed in Sweden, Denmark and UK carry out extensive evidence reviews.
- We describe more carefully the most relevant limitations/shortcomings of the present study.

Any further responses from the reviewers can be found at the end of the article.
We excluded systematic reviews that did not meet the criteria for the above-mentioned PICO:

- Children and adolescents with other main-diagnosis, e.g. children admitted to hospitals because of somatic illness at the same time as experiencing depressive symptoms.
- Interventions with the main objective to prevent other mental health problems, such as depression.
- Interventions preventing other behaviours with no direct association with mental health, e.g. interventions targeting smoking cessation.
- Pharmaceutical interventions compared to placebo. This review was conducted to inform decision-making in Norway, and for this purpose only direct comparisons between pharmaceutical treatments were judged to be relevant.

### Literature search

The literature search for this review was completed in August 2018 and is largely based on IN SUM: a database of systematic reviews on effects of child mental health and welfare interventions.23 We reviewed all references indexed in IN SUM. IN SUM indexes reviews related to children’s and young people’s mental health from the following databases: Cochrane Database of Systematic Reviews, Campbell Library, PsycINFO, MEDLINE, Embase, Web of Science, Database of Abstracts of Reviews of Effects (DARE) and Evidence Based Mental Health (see extended data) for a description of the IN SUM search strategy, including search words). Examples of search words were suicid*, selfharm*, selfharm*, intervention*, strategy, therap*, child*, adoles*.

The present overview of systematic reviews was developed following the principles of the Cochrane handbook. Two researchers independently reviewed all publications indexed in IN SUM (two of the authors: AD or ISM, and/or a research colleague KTH). Supplementing the references found in IN SUM, we also hand-searched for relevant systematic reviews, in the following databases and organizations:

- The Norwegian Institute of Public Health
- The Swedish agency for health technology assessment and assessment of social services (SBU)
- The Norwegian Directorate of Health
- The Danish Health Authority
- The National Institute for Health and Care Excellence (NICE)

All publications judged to meet the inclusion criteria were retrieved in full text. Two researchers (ISM, AA) independently screened and assessed all full text reviews for potential inclusion. In cases of disagreement, we consulted a third person.

### Assessment of overlap between reviews and methodological quality

We sorted all included reviews by population and intervention comparisons (the PICOs). In cases were more than one review addressed the same comparison for the same population, we included the review with the newest search date (and completeness of this search by considering the included primary studies) and the best quality. In considering overlap, the first author (ISM) extracted this information from the reviews, and the second author (AA) double-checked the information. Further, we assessed the methodological quality of the included reviews based on a checklist for systematic reviews (AMSTAR: A MeaSurement Tool to Assess systematic Reviews). Two people (ISM, IB) considered each publication independently and decided on the quality through discussions until consensus.

The final decision on which reviews to include was done through agreement between two of the authors (ISM and AA). Table 1 contains documentation on characteristics of the included reviews, including methodological quality.

### Data extraction and analyses

ISM extracted data from the systematic reviews and AA checked its accuracy. As this was an overview of systematic reviews, we extracted information as it was reported in the systematic reviews, including any supplementary tables or appendixes. We did not retrieve primary studies to provide additional information about interventions or results.

From the systematic reviews, we extracted information about the primary studies’ populations, characteristics of the interventions and comparison groups, duration of the interventions, follow-up periods, outcome measures and pooled effect estimates for each outcome. In cases were the effect estimates were not pooled in a meta-analysis, we reported the results of each individual study for each outcome.

We did not attempt any reanalysis, but present results as reported in the systematic reviews. For reviews including studies on both children/adolescents and adult populations,

| **Interventions for existing self-harm: developmental group therapy versus TAU**  
**Population:** Adolescents, 12 to 17-year olds, referred to child and adolescent services following an episode of intentional self-injury or self-poisoning, irrespective of intent  
**Intervention:** Manualized developmental group psychotherapy involving elements of cognitive behavioural therapy, social skills training, interpersonal psychotherapy, dialectical behaviour therapy, and group psychotherapy with or without addition to treatment as usual  
**Control:** Treatment as usual (i.e. individual counselling, family individual-based interventions such as counselling, family sessions, pharmaceutical treatment)  
**Length of intervention:** Acute treatment phase weekly sessions over 6 weeks, followed by weekly or biweekly booster sessions as long as required  
**Follow-up period:** 6 and 12 months | | | | |
| **Interventions for existing self-harm: other psychotherapeutic approaches (no primary studies identified)** | | | | |
| **Interventions for existing self-harm: nutrition**  
No primary studies identified | | | | |
| **Interventions for existing self-harm: pharmacological treatment**  
No primary studies identified | | | | |
| **Interventions for existing self-harm: compliance enhancement versus TAU**  
**Population:** Children and adolescents, 10 to 19-year olds, admitted to the emergency department of a general hospital following an episode of self-injury irrespective of intent, and/or increased risk for suicidality  
**Intervention:** a single, one-hour session that reviewed expectations for outpatient treatment as well as addressing factors likely to impede attendance and treatment misconceptions and encouraged both the adolescent and parent to make verbal contract and to attend all treatment sessions. Follow-up phone-calls 1, 2, 4 and 8 weeks after disposition.  
**Control:** TAU  
**Length of intervention:** 8 weeks  
**Follow-up period:** 3 months | | | | |
| **Interventions for existing self-harm: home-based family intervention versus TAU**  
**Population:** Adolescents aged 16 or younger referred to child and adolescent mental health services following an episode of self-poisoning irrespective of intent  
**Intervention:** manualized home-based family therapy intervention involving one assessment session and 4 home visits in addition to treatment as usual  
**Control:** Treatment as usual  
**Length of treatment:** Not stated  
**Follow-up period:** 6 months | | | | |
| **Interventions for existing self-harm: emergency cards plus TAU versus TAU**  
**Population:** adolescents in the ages of 12 to 16 admitted to hospital after an episode of self-injury or self-poisoning  
**Intervention:** emergency green card in addition to usual care. The green card acted as a passport to re-admission into a paediatric ward at the local hospital  
**Control:** standard follow-up including treatment from a clinic or child psychiatry department as required  
**Length of intervention:** 12 months  
**Follow-up period:** 12 months | | | | |

| NICE 2018 | Suicide preventing interventions in different arenas | School-based suicide prevention programs versus TAU, alternative interventions, wait list or no intervention  
**Population:** School-aged children and adolescents between the ages of 10 and 23 and personnel working with young people (in schools and other local arenas)  
**Intervention:** School based programs (e.g. Signs of Suicide/SoS, Garrett Lee Smith Youth Suicide Prevention Program/GLS), in which the adolescents and personnel in schools and other local arenas learned about suicide  
**Control:** Wait list, alternative interventions (information on posters in the classrooms) or no intervention (counties in which GLS was not implemented)  
**Length of intervention:** Not stated  
**Follow-up period:** 3 to 12 months  
**Primary prevention: reducing access to means**  
No primary studies identified  
**Primary prevention: local suicide plans**  
No primary studies identified  
**Secondary prevention: local approaches to suicide clusters versus historical control**  
**Population:** Children, adolescents and young adults between the ages of 10 and 24  
**Intervention:** Interventions focusing on how the psychiatric services responded after suicide clusters, including debriefing from clinicians giving information, identifying individuals with an increased risk of self-harm, individual screening, and crisis evaluation  
**Control:** Historical  
**Length of intervention:** Not stated  
**Follow-up period:** 4 years  
**Primary prevention: local media reporting of suicides in newspapers, Internet or other digital channels versus historical control**  
**Population:** Population based sample, a wider age-range than children and adolescents  
**Intervention:** One study examining suicides before or after a news story, the other effects of a new guideline for media reporting of suicides  
**Control:** Historical  
**Length of intervention:** Not stated  
**Follow-up period:** Not stated  
**Interventions to prevent suicide in residential custodial and detention settings**  
No primary studies identified  
**Secondary prevention: interventions to support children and adolescents bereaved or affected by a suspected suicide versus TAU or historical control**  
**Population:** Children and adolescents in primary and secondary school (under the age of 17) that have lost a friend or parent to suspected suicide  
**Intervention:** Bereavement group intervention, weekly meetings led by a psychologist  
**Control:** Treatment as usual (no bereavement group) or historical  
**Length of intervention:** 10 weeks  
**Follow-up period:** Not stated  
**Primary prevention: screening for suicide risk versus no screening**  
**Population:** Adolescents between the ages of 13 and 19  
**Intervention:** Screening of symptoms of depression and a history of self-harm, suicidal ideation or suicide attempts  
**Control:** No screening  
**Length of intervention:** Not stated  
**Follow-up period:** Not stated | 11 | >19th of October 2018 | No restrictions |
we only extracted information from studies on children and adolescents. When reported, the effect estimates were presented with relevant measures of uncertainty.

Assessing the certainty of evidence and reporting of results
We assessed our confidence in the evidence of effect for each outcome using the GRADE methodology (the Grading of Recommendations Assessment, Development and Evaluation)^28. If the systematic review authors already had completed a GRADE assessment, we reviewed this. We describe our confidence in the effect estimates as high, moderate, low or very low for each outcome.

Results
Results of the literature search
All 1259 references in the INSUM database was reviewed for potential relevance (see Figure 1). Additionally, we identified 12 records through hand-searches. Of the all together 1271
references, we excluded 1242 based on title or summary, mainly because they focused on other diagnosis or problem-areas than self-harm and/or suicide. Overall, 29 full texts were retrieved, 12 were excluded because they did not fulfil the inclusion criteria. Out of 18 potentially included reviews, 9 were excluded because of overlap (see Table 2 for excluded studies).

Figure 1 describes the search-process and the number of articles excluded in each step. Eight systematic reviews were included in the analysis. One review was identified after we had completed the analysis and is therefore not included in the present review of systematic reviews.

Although the initial cut-off for age in our population was 18, two of the reviews included studies with young people up to 24. These were included because the upper age limit used to define adolescence in research on self-harm and suicides varies between 18 and 25.

Assessment of quality of systematic reviews
The eight included systematic reviews were assessed for quality (see Table 1). Overall, the reviews were of high methodological quality, even though some of the reviews lacked a priori design, systematic searches for grey literature and assessment of publication bias. We appraised three systematic reviews with AMSTAR-scores in the range of 6–8, and the remaining five with AMSTAR-scores in the range of 9–11.

Description of interventions
The reviews included a broad range of interventions. Most of the studies included adolescent populations in the age-range 12 to 18, with some exceptions of samples including younger children or young adults up to the age of 24. Preventive interventions were either focused on primary prevention for mixed-age population based samples (suicide awareness campaigns and other school-based prevention programs, screening for suicide risk) or secondary prevention (local approaches following
Table 2. Systematic reviews excluded after full text assessment.

suicide clusters, suicide prevention in residential custodial and detention settings, interventions to support children and adolescents bereaved or affected by a suspected suicide\textsuperscript{17,29,30}. The reviews also included psychosocial or psychological intervention in cases of existing self-harm (defined as a history of at least one episode of self-harm) (therapeutic assessment, mentalization based therapy, dialectic behaviour therapy, cognitive behaviour therapy, developmental group therapy, compliance enhancement, home-based family intervention, emergency green cards, digital interventions for self-management of suicidal ideation and self-harm, postcards)\textsuperscript{16,30,31,34}.

**Summary of findings**

The effects of interventions are presented by type population (young people with or without an identified risk, or with existing self-harm, e.g. a history of at least one episode of self-harm) and by treatment comparison. Our assessment of certainty of evidence corresponds to GRADE-tables in Table 3–Table 16. For comparisons with many outcomes, we report the main outcomes in the present results section. See GRADE-assessments in Table 3–Table 16 for the remaining outcomes.

The review authors also searched for research on effects of the following interventions (versus treatment as usual (TAU) or alternative interventions), but studies on children and adolescents under the age of 18 were not identified. These were primary and secondary preventive interventions (reducing access to means, local suicide plans, local media reporting of suicides in newspapers, Internet or other digital channels, suicide prevention in residential custodial and detention settings)\textsuperscript{35} and interventions targeting existing self-harm (assessment in children and adolescents at the emergency department, psychoeducation, pharmacological treatment or a combination of pharmacological treatment and psychotherapy, nutrition, other psychotherapeutic approaches such as problem-solving therapy, psychodynamic therapy, multi-systemic therapy, supportive therapy, or other psychosocial approaches such as counselling, self-management, respite care, assertive outreach)\textsuperscript{13–38}.

**Preventive interventions**

**School-based suicide prevention programs versus TAU, alternative interventions, wait list or no intervention.** The evidence includes 13 studies with <337 221 children and adolescents aged 10 to 23, as well as personnel in different local arenas working with young people\textsuperscript{13–29}. In one of the studies, the participants (n=320 500) were habitants in a county in which county-based prevention programs were implemented. These participants included school students and personnel in schools and other local arenas. School-based prevention programs probably reduce suicidal ideation (RR 0.67, 95% KI 0.48 to 0.93, moderate certainty\textsuperscript{10}⊕⊖⊖⊖, moderate certainty\textsuperscript{10}⊖⊖⊖⊖) and suicide attempts (RR 0.53, 95% KI 0.36 to 0.80, moderate certainty\textsuperscript{10}⊕⊖⊖⊖) at three to 12 months. Regarding suicide attempts, three studies conclude accordingly at six- and 12-month follow-up period. This effect possibly holds at ≥two- and 15-year follow-up (low certainty\textsuperscript{10}⊕⊖⊖⊖). Further, school-based interventions possibly reduce the rate of completed suicides at three-year follow-up (low certainty\textsuperscript{10}⊕⊖⊖⊖). Effects on help-seeking and unwanted effects are unclear since the evidence for these outcomes is of very low certainty\textsuperscript{10}⊖⊖⊖⊖. See Table 3.

**Primary prevention: local approaches following suicide clusters versus historical control.** The evidence includes three studies with children and adolescents between the ages of 10 and 24\textsuperscript{29}. Follow-up period was up to four years. The evidence of effects of local approaches following suicide clusters is of very low certainty\textsuperscript{10}⊖⊖⊖⊖. See Table 4.

**Secondary prevention: interventions to support children and adolescents bereaved or affected by a suspected suicide compared to TAU or historical control.** The evidence includes two studies\textsuperscript{29}. However, the evidence of effects of interventions to support children and adolescents bereaved or affected by a suspected suicide is of very low certainty\textsuperscript{10}⊖⊖⊖⊖. See Table 5.

**Primary prevention: screening for suicide risk versus no screening.** The evidence is based on one review\textsuperscript{29}. The review authors did not identify studies evaluating beneficial effects of screening as a preventive strategy in children or adolescents. They did however identify two studies evaluating adverse effects associated with screening for psychological distress and a history of deliberate self-harm and suicidal ideation in primary care settings. The studies comprised of 2650 adolescents between 13 and 19 years old, and the evidence is of very low certainty\textsuperscript{10}⊖⊖⊖⊖. See Table 6.

**Interventions for existing self-harm: therapeutic assessment versus TAU.** The evidence includes one study with 70 adolescents, 12 to 18-year olds referred for a psychosocial assessment following an episode of self-injury or self-poisoning, irrespective of intent\textsuperscript{17}. Length of intervention was one hour and 40 minutes. Follow up was 12 and 24 months. The evidence of effects of therapeutic assessment is of very low certainty\textsuperscript{10}⊖⊖⊖⊖. See Table 7.

**Interventions for existing self-harm: mentalization based therapy (MBT-A) versus TAU.** The evidence includes one study with 80 adolescents, 12 to 17-year olds, diagnosed with depression and presenting to emergency departments or community psychiatric services following an episode of self-injury or self-poisoning, irrespective of whether suicidal intent was present\textsuperscript{29}. Length of treatment was 12 months, and follow-up period was also 12 months. The evidence of effects of therapeutic assessment is of very low certainty\textsuperscript{10}⊖⊖⊖⊖. See Table 8.
### Table 3. GRADE-assessment: School-based suicide prevention programs versus treatment as usual (TAU), alternative interventions, wait list or no intervention.

Population: Children and adolescents between the ages of 10 and 23, as well as personnel working with young people in schools and other arenas

Intervention: School-based suicide prevention programs

Control: TAU, alternative interventions, wait list or no intervention

Based on: NICE 2018 and SBU 2014

1. Downgraded by 1 level due to risk of bias (no blinding).
2. Downgraded by 1 level due to imprecision (few participants).
3. Downgraded by 1 level due to imprecision (only 1 study).

However, DBT-A may have a moderate effect on reduction of suicidal ideation (SMD -0.62, 95% KI -1.07 to -0.16, low certainty ⊕⊕☉☉). The certainty of evidence for other outcomes is very low⊕☉☉☉. See Table 9.

Interventions for existing self-harm: cognitive behaviour therapy (CBT) versus non-directive psychotherapy. The evidence contains one study with 39 adolescents between the age of 12 and 17 presenting to a paediatric general or psychiatric facility following self-injury in which an intent to die was indicated11. Length of treatment was six months. Follow-up period was three, six and 12 months. The certainty of evidence for effects of CBT compared to non-directive psychotherapy is very low⊕☉☉☉. See Table 10.
Interventions for existing self-harm: developmental group therapy versus TAU. The evidence contains three studies with 487 adolescents, 12 to 17-year olds, referred to child and adolescent services following an episode of intentional self-injury or self-poisoning, irrespective of intent. The acute treatment phase was six weekly sessions, followed by weekly or biweekly booster sessions for as long as required. Follow-up period was between six and 12 months. Based on the available evidence, the effects of developmental group therapy compared to TAU are uncertain on the following outcomes: repetition of self-harm (six months: OR 1.72 95% KI 0.56-5.24, 12 months: OR 0.80 95% KI 0.22 to 2.97), depression (six months: MD 0.40 95% KI -2.76 to 3.55, 12 months: MD -0.93 95% KI -4.03 to 2.17), suicidal ideation (six months: MD 1.27 95% KI -7.74 to 10.28, 12 months: MD -1.51 95% KI 9.62 to 6.59) or suicide (no suicides). The evidence for all the outcomes is of low certainty. See Table 12.

Interventions for existing self-harm: home-based family intervention versus TAU. The evidence contains one study in a sample of adolescents aged 16 years or younger referred to child and adolescent mental health services following an episode of self-poisoning irrespective of intent. The intervention was a manualized home-based family therapy intervention. Follow-up period was six months. The evidence of effects of home-based family intervention is of very low certainty. See Table 13.

Interventions for existing self-harm: emergency green cards plus TAU versus TAU. The evidence contains one study with 105 adolescents between the ages of 12 and 16 who were admitted to hospital following an episode of self-injury or self-poisoning. The intervention was emergency green cards in addition to usual care. The green card acted as a passport to re-admission into a paediatric ward at the local hospital. Length of treatment was 12 months. Follow-up period was 12 months. The evidence of effects of emergency green cards is of very low certainty. See Table 14.

### Adverse effects

- Not reported

---

1. Downgraded by 1 level due to risk of bias (no blinding).
2. Downgraded by 1 level due to imprecision (few participants/incidences).
3. Downgraded by 1 level due to imprecision (only 1 study).

Population: Adolescents, 12 to 17-year olds, diagnosed with comorbid depression presenting to emergency departments or community psychiatric services following an episode of self-injury or self-poisoning, irrespective of whether suicidal intent was present.

Intervention: Mentalization based therapy for adolescents (MBT-A)

Control: TAU

Based on: Hawton 2015

Interventions for existing self-harm: compliance enhancement versus TAU. The evidence contains one study of 76 adolescents, 12 to 19-year olds, admitted to the emergency department of a general hospital following an episode of self-injury, irrespective of intent, and/or with an increased risk for suicidality. Length of treatment was eight weeks. Follow-up period was three months. The evidence of effects of compliance enhancement is of very low certainty. See Table 12.
Table 9. GRADE-assessment: Interventions for existing self-harm: dialectical behaviour therapy adapted for adolescents (DBT-A) versus treatment as usual (TAU) or enhanced TAU.

Population: Adolescents, 12 to 19-year olds, with a history of multiple episodes of self-harm
Intervention: Dialectical behaviour therapy for adolescents (DBT-A)
Control: TAU or enhanced TAU
Based on: Hawton 2015

Poisons hospital after self-poisoning. The other review included one study of 165 adolescents and young adults of 15 to 24 years old with a history of suicidal threats, ideation, attempts and/or self-injury who did not meet entry criteria for service because they either were not unwell enough or were receiving treatment elsewhere. Follow-up was post study. The evidence of effects of postcards is of very low certainty⊕⊖⊖⊖. See Table 16.

### Discussion

The present paper gives a comprehensive overview of effects of interventions aimed at preventing self-harm and suicide in children and adolescents. We found evidence to suggest that school-based interventions probably prevent suicidal ideation and suicide attempts short term, and possibly suicide attempts long term. The effects of community-based interventions following suicide clusters and local suicide plans are unknown, as are...

the benefits and harms of screening young people for suicide risk. The effects of most interventions targeting children and adolescents with known self-harm are also unknown. However, low certainty evidence suggests that dialectical behavioural therapy and developmental group therapy are equally as effective on repetition of self-harm as enhanced treatment as usual. In general, the populations are adolescents in the age-range of 12 to 18 years.

Effects of preventive interventions: summary of findings and implications

Based on the available research, school-based interventions can prevent suicidal ideation and suicide attempts short term (moderate certainty evidence), and possibly suicide attempts long term (low certainty evidence), which should have obvious implications for policy makers.

As regards other preventive strategies, there is a general a lack of research on effects of recommended practices, such as approaches to risk assessment and local suicide plans. Screening for suicide risk as primary prevention may provide the opportunity of early detection, and if precise, offer the opportunity to provide young people at risk with appropriate treatment. However, it is resource demanding, and based on available research, effects of screening children and young people for symptoms of depression and a history of self-harm or suicidal ideation in the general population are unknown, given very low certainty evidence. Local suicide plans are a recommended strategy in some countries. However, the effects of such plans on preventing self-harm and suicide in children and young people is yet to be evaluated in research. Therefore, when implemented, approaches to risk assessment and screening programs, as well as local suicide plans, should be closely evaluated.

We identified no reviews evaluating the effects of reducing access to means from children and young people specifically, or on how media reporting of suicides affects suicide rates in children and young people. In these instances, studies on interventions targeting the general population could be informative. Such studies suggest that reducing access to means may be an effective strategy, and that certain forms of media reporting
are associated with an increase in suicides. Guidelines on how to report on suicides is one suggested strategy to address the possible harms of such reporting.

Suicide clusters, although rare, is a phenomenon of major concern. When faced with potential social contagion following suicide, communities are expected to act to prevent contagion and clustering. However, based on a few studies, the certainty of evidence for community-based interventions following suicide clusters is very low, as is the evidence on effects of support-interventions in young people bereaved or affected by a suicide in their family or other network. Even so, recommendations are agreed upon, e.g. provision of information to relevant agencies in the community and providing support for those directly affected or other vulnerable individuals.

However, given that the above-mentioned research is of very low certainty, we suggest that researchers design appropriate observational studies, allowing for enough observations pre- and post-implementation of preventive measures to inform policy.

The reviews we identified also searched for studies targeting young people in residential custodial and detention settings, but no studies were identified. Therefore, effects of interventions in this high-risk population are uncertain.

**Effects of interventions for existing self-harm: summary of findings and implications**

Self-harm is a common reason for referral of adolescents in child and adolescent psychiatric services, and often accompanies other psychiatric symptoms presented in such settings. However, based on the available evidence, only two treatment comparisons evaluating psychological therapy provided evidence of their effectiveness (low certainty); dialectical behavioural therapy and developmental group therapy. Both treatments were compared to enhanced TAU (e.g. individual

and family sessions, medication management, and hospital or respite care as required), and there was little or no important difference in effect on repetition of self-harm, nor on symptoms of depression. However, of notice, although not statistically significant, there was a substantial higher degree of repetition of self-harm amongst adolescents participating in group developmental therapy compared to those receiving enhanced TAU at six-month follow-up. At 12-month follow-up, there was little or no important effect on self-harm. Clinicians should be aware of this potential short-term adverse effect, but this should be investigated in future studies. However, the findings on beneficial effects are overall promising. It seems that both
dialektische Verhaltensbehandlung und developmentaler Gruppentherapy, or established treatment approaches, are good treatment alternatives.

For remaining interventions targeting self-harm, effects are unknown. It is uncertain which approach to risk assessment of young people after an episode of self-harm is most appropriate given low certainty evidence. Furthermore, the effects of psychosocial interventions, digital interventions for self-management and nutrition for treating young people with existing self-harm are unknown, as no studies were identified.

The reviews we included searched for, but did not identify, studies on direct comparisons between different pharmacological treatment alternatives or on the effects of combination therapy (pharmacological treatment plus psychotherapy). The finding that biological factors may be associated with, or

even predict, a suicide attempt could have implications for research on pharmacological agents.

The evidence of effects of organization of services, such as home-based treatment and use of emergency green cards, is of very low certainty. New research in this area is pertinent, especially for policy makers.

Limitations
A limitation of overviews of reviews, and consequently of the present paper, is that the analyses are based on secondary reporting of what the review authors interpreted and reported based on the primary studies. It follows that the primary studies may have provided more information than what is reported in the reviews we included. A primary study investigating e.g. treatment attendance would be relevant to a clinician wanting to meet with a client struggling with suicidality regularly in order to build a working alliance. However, if the review authors did not find such an outcome from a primary study relevant, we will have missed this information. Regardless of this limitation, the reader of our overview of reviews could find a particular primary study referenced in the included review, if there is need to check if the primary study investigated other relevant outcomes.

It is also worth noting that the present paper only included reviews of studies where the intervention was to prevent or treat self-harm and suicide in children and adolescents, with exception of a few population-based studies. Self-harm and suicide are associated with other difficulties such as psychosis, depression and anxiety. Therefore, evidence from studies on children and adolescents at risk for or diagnosed with such conditions may provide important direction in decision-making when faces with self-harm and suicide. However, in studies on these conditions, self-harm and suicide are rarely investigated as outcomes. An exception is research on depression, with low certainty evidence indicating that combination treatment for depression (pharmacological treatment plus psychotherapy) may lead to a reduced risk for suicide.

Conclusions
Overall, evidence of moderate to low certainty suggests that school-based suicide prevention programs can prevent suicide and suicide attempts in young people. The effects of community-based interventions following suicide clusters and local suicide plans are uncertain. Furthermore, it is not possible to make any conclusions about the benefits or harms of screening in young people with or without known risk of self-harm and suicide.

When it comes to treatment strategies for young people with existing self-harm, evidence of low certainty suggests that dialectical behavioural therapy and developmental group therapy are equally effective on repetition of self-harm as enhanced treatment as usual (often individual and/or family psychotherapy). The effects of other interventions specifically targeting self-harm are unknown, because of lack of research or evidence of very low certainty, and should be evaluated. These interventions include mentalization-based psychotherapy, cognitive behavioural therapy and psychodynamic therapy.

Collectively, due to a general lack of research, and in some cases very low certainty evidence, the effects of most interventions are unknown. This has several implications. First and foremost, more research is needed, including studies on children younger than 12 years of age, as well as long-term follow up. Second, when implementing recommended practice with unknown effects, such as approaches to risk assessment, practice should be closely evaluated. With all types of interventions, there is a possibility for adverse effects. Hence, it is crucial to be mindful that our own preventive actions or treatment efforts could contribute to an increased risk for self-harm and suicide, and both adverse as well as beneficial effects should be evaluated. Third, policy makers and health providers should consider evidence from other relevant populations in decision-making, such as studies on adults, as well as studies on conditions associated with self-harm and/or suicidality, e.g. depression and psychosis.

A final implication worth mentioning is related to the scope of the present review of systematic reviews: effects of interventions. In decision-making, knowledge of effects of interventions should be supplemented with other relevant research, such as therapeutic processes influencing the outcome, as well as integrated with clinical expertise and the child’s and adolescent’s and caregiver’s values and preferences.

Thank you for asking me to review again the present manuscript. In the revised paper, the authors addressed, in my opinion, most of the major comments raised by reviewers improving both the main structure and quality of the present paper. I have no further additional comments.

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Psychopathology and neurobiology of suicidal behavior and major affective disorders.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

Gianluca Serafini
Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics and Maternal and Child Health, University of Genoa, Genoa, Italy
Thank you very much for asking me to review the present manuscript.

This is, in summary, an interesting paper aimed to evaluate the effects of interventions preventing self-harm and suicide in children and adolescents in an overview of systematic reviews. The authors reported that (moderate certainty evidence) school-based interventions prevent suicidal ideation and attempts short term, and possibly with long term effects on suicide attempts. Overall, the effects of community-based interventions following suicide clusters and local suicide plans resulted uncertain, as are the benefits and harms of screening young people for suicide risk. In addition, the effects of most interventions targeting children and adolescents with known self-harm were uncertain. They added that (low certainty evidence) dialectical behavioural therapy and developmental group therapy are equally as effective on repetition of self-harm as enhanced treatment as usual.

The authors may find as follows my main comments/suggestions:

First, as the authors, throughout the Introduction section, correctly stated that self-harm and suicide are associated with relevant psychosocial impairment and result from underlying factors such as other mental health problems, exposure to traumatic events or other difficult circumstances in the young person’s environment, they might even mention that the emotional turmoil in the case of suicide survivors of patients died by suicide may last a long time, and in some cases, may end with their own suicide. Thus, together with self-harm and suicide, it is fundamental to understand the bereavement process after the suicide of a significant other to provide a proper care, reduce stigma, and improve the outcomes. In addition, specific biological factors such as prolactin and thyroid hormone levels may be dysregulated and significantly associated with self-harm and suicide attempts and even involved in a complex compensatory mechanism to correct reduced central serotonin activity. The assumption that prolactin and thyroid hormones may be associated or even predict a suicide attempt is of great importance given the availability of such data in everyday clinical practice. Physicians of any kind as well as mental health professionals should be aware of the importance to insert as much information possible in the assessment of suicide and self-harm risk. Thus, given the above mentioned information, the authors could include throughout the manuscript, some published papers regarding the mentioned topics (PMID: 24082246; 31091772; 28843902; 22748186; 12866334)\textsuperscript{12345}.

In addition, why the authors decided to include all publications in English, Norwegian, Danish or Swedish rather than simply including only studies in English language is a matter of debate and needs to be specified.

Moreover, the authors should immediately present and discuss, in the first lines of the Discussion section, their most relevant study findings. Conversely, they seem to focus with redundancy on the main aims/objectives of the paper which have been already presented elsewhere.

Although the authors reported that the present analyses are based on secondary reporting and the interpretation of the review authors as well as that the present report included only reviews of studies where the population was children and young people with existing self-harm, the most relevant limitations/shortcomings of the present study need to be more carefully described for the general readership.

Finally, what is the take-home message of this manuscript? While the authors stated that practice should be evaluated, and researchers should investigate harmful effects as well as beneficial effects of interventions, they failed, in my opinion, to provide some conclusive remarks about their findings. Here, some further details/information are needed.
References

Are the rationale for, and objectives of, the Systematic Review clearly stated?
Yes

Are sufficient details of the methods and analysis provided to allow replication by others?
Yes

Is the statistical analysis and its interpretation appropriate?
Not applicable

Are the conclusions drawn adequately supported by the results presented in the review?
Yes

**Competing Interests:** No competing interests were disclosed.

**Reviewer Expertise:** Psychopathology and neurobiology of suicidal behavior and major affective disorders.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.

Author Response 10 Feb 2020

**Ida Sund Morken**, Regional Centre for Child and Adolescent Mental Health, Eastern and Southern Norway (RBUP), Oslo, Norway

1) First, as the authors, throughout the Introduction section, correctly stated that self-harm and suicide are associated with relevant psychosocial impairment and result from underlying factors such as other mental health problems, exposure to traumatic events or other difficult circumstances in the young person’s environment, they might even mention that the emotional turmoil in the case of suicide survivors of patients died by suicide may last a long time, and in some cases, may end with their own suicide. Thus, together with self-harm and suicide, it is fundamental to understand the bereavement process after the suicide of a significant other to provide a proper care, reduce stigma, and improve the outcomes. In addition, specific biological factors such as
Prolactin and thyroid hormone levels may be dysregulated and significantly associated with self-harm and suicide attempts and even involved in a complex compensatory mechanism to correct reduced central serotonin activity. The assumption that prolactin and thyroid hormones may be associated or even predict a suicide attempt is of great importance given the availability of such data in everyday clinical practice. Physicians of any kind as well as mental health professionals should be aware of the importance to insert as much information possible in the assessment of suicide and self-harm risk. Thus, given the above mentioned information, the authors could include throughout the manuscript, some published papers regarding the mentioned topics (PMID: 24082246; 31091772; 28843902; 22748186; 12866334).

- Thank you for interesting suggestions. We have added information and some of the recommended citations in the introduction regarding the importance of bereavement as a risk factor in prevention of suicide, as well as in the section on “Effects of preventive interventions: summary of findings and implications”, and about biological factors as possible risk factors in the introduction, as well as in “Effects of interventions for existing self-harm: summary of findings and implications”.

2) In addition, why the authors decided to include all publications in English, Norwegian, Danish or Swedish rather than simply including only studies in English language is a matter of debate and needs to be specified.
- We thank reviewer 2 for pointing this out, and have added information about why choosing English, Norwegian, Danish or Swedish rather than simply including only studies in English language. For pragmatic reasons, we have included languages available to us. Furthermore, guidelines developed in Sweden, Denmark and UK carry out extensive evidence reviews. Neglecting to include these would weaken the evidence base.

3) Moreover, the authors should immediately present and discuss, in the first lines of the Discussion section, their most relevant study findings. Conversely, they seem to focus with redundancy on the main aims/objectives of the paper which have been already presented elsewhere.
- We agree, and are now more focused on our main findings in the beginning of the discussion.

4) Although the authors reported that the present analyses are based on secondary reporting and the interpretation of the review authors as well as that the present report included only reviews of studies where the population was children and young people with existing self-harm, the most relevant limitations/shortcomings of the present study need to be more carefully described for the general readership.
- We now described more carefully the most relevant limitations/shortcomings of the present study, including examples of what we mean, so that the limitations become more apparent.

5) Finally, what is the take-home message of this manuscript? While the authors stated that practice should be evaluated, and researchers should investigate harmful effects as well as beneficial effects of interventions, they failed, in my opinion, to provide some conclusive remarks about their findings. Here, some further details/information are needed.
- Thank you, and we agree. We now have the take-home message as well as some further details/information in conclusive remarks about the finding in the conclusion.

**Competing Interests:** No competing interests were disclosed.
The article evaluates the effects of self-harm and suicide prevention interventions for children and adolescents. The rationale behind the study is sufficiently supported by different research. The methodology provided is sufficient except it is unclear why only systematic reviews published in 2012 or later are included. It is also unclear what search terms were used for future replications.

The authors report a range of outcome measures in the results that may not be directly related to self-harm. Such outcomes (e.g. treatment engagement) were not further commented on or summarised. Overall, the systematic review is very comprehensive but the discussion and summary could be more coherent and with a better flow. For instance, the authors can attempt to comment on the implications of TAU control group versus other active intervention control groups.

Are the rationale for, and objectives of, the Systematic Review clearly stated?
Yes

Are sufficient details of the methods and analysis provided to allow replication by others?
Partly

Is the statistical analysis and its interpretation appropriate?
Not applicable

Are the conclusions drawn adequately supported by the results presented in the review?
Yes

**Competing Interests:** No competing interests were disclosed.

**Reviewer Expertise:** Clinical psychology, mainly child and adolescent mental health, specifically self-harm or autism.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.
1) The methodology provided is sufficient except it is unclear why only systematic reviews published in 2012 or later are included.

   · We thank reviewer 1 for pointing out that this was unclear. This cut-off is pragmatic but similar to that practiced by others, for example, the Cochrane Library (https://community.cochrane.org/editorial-and-publishing-policy-resource/cochrane-review-developmne in considering that an older review is obsolete and no longer a reliable basis for evidence and in need for being updated. It takes time before a review is published, consequently a review may be published one to three years later than the search was done for primary studies. This has improved with time and new publication standards for reviews. Thus, a review published earlier than 2012 may not include primary studies published the last >10 years. A sentence to explain this has now been added to the manuscript.

2) It is also unclear what search terms were used for future replications.

   · The literature search for this review was completed in August 2018 and is largely based on IN SUM: a database of systematic reviews on effects of child mental health and welfare interventions. We reviewed all references indexed in IN SUM. IN SUM indexes reviews related to children’s and young people’s mental health from the following databases: Cochrane Database of Systematic Reviews, Campbell Library, PsycINFO, MEDLINE, Embase, Web of Science, Database of Abstracts of Reviews of Effects (DARE) and Evidence Based Mental Health. A description of IN SUMs searching strategy is included in extended data. We have now made it explicit that the search-words are included in the IN SUM Search Strategy (extended data, reference 22), we provide examples of search words, and we point out that we screened all the references in IN SUM.

3) The authors report a range of outcome measures in the results that may not be directly related to self-harm. Such outcomes (e.g. treatment engagement) were not further commented on or summarised.

   · Thank you for pointing this out, as research on other outcomes are often highly relevant. For this review we included all outcomes as reported by the review authors. Effect estimates and judgements of certainty for each such outcome is reported for all pooled estimates. However, in line with the GRADE recommendations, we only make conclusions on outcomes judged to be of low, moderate or high certainty. When evidence is of very low certainty, the effects of these outcomes are considered to be too uncertain as to make any conclusions.

4) Overall, the systematic review is very comprehensive but the discussion and summary could be more coherent and with a better flow. For instance, the authors can attempt to comment on the implications of TAU control group versus other active intervention control groups.

   · Thank you for this feedback. We have now tried to make the discussion and summary more coherent, see introduction, discussion and summary. We have also commented on the implications of TAU control group versus other active intervention control groups, see “Effects of interventions for existing self-harm: summary of findings and implications”.

**Competing Interests:** No competing interests were disclosed.

Author Response 06 Feb 2020

Ida Sund Morken, Regional Centre for Child and Adolescent Mental Health, Eastern and Southern Norway (RBUP), Oslo, Norway

Thank you for making us aware of this relevant new publication, which is an important addition to existing reviews in this field. We have added your publication to our list of pending references to be considered if we decide to update our review.

Competing Interests: No competing interests were disclosed.

Reader Comment 01 Jul 2019

Eleanor Bailey, Orygen, The National Centre of Excellence in Youth Mental Health, Australia

I'm not sure if the authors are aware, but our group recently published a systematic review and meta-analysis of interventions to prevent suicide in young people - available here https://www.thelancet.com/journals/eclinm/article/PIIS2589-5370(18)30041-5/fulltext. It may be worthwhile including this in your review of reviews!

Competing Interests: No competing interests were disclosed.

The benefits of publishing with F1000Research:

- Your article is published within days, with no editorial bias
- You can publish traditional articles, null/negative results, case reports, data notes and more
- The peer review process is transparent and collaborative
- Your article is indexed in PubMed after passing peer review
- Dedicated customer support at every stage
