**Abstract**

All species are hierarchically related to one another, and we use taxonomic names to label the nodes in this hierarchy. Taxonomic data is becoming increasingly available on the web, but scientists need a way to access it in a programmatic fashion that’s easy and reproducible. We have developed taxize, an open-source software package (freely available from [http://cran.r-project.org/web/packages/taxize/index.html](http://cran.r-project.org/web/packages/taxize/index.html)) for the R language. taxize provides simple, programmatic access to taxonomic data for 13 data sources around the web. We discuss the need for a taxonomic toolbelt in R, and outline a suite of use cases for which taxize is ideally suited (including a full workflow as an appendix). The taxize package facilitates open and reproducible science by allowing taxonomic data collection to be done in the open-source R platform.

Introduction

Evolution by natural selection has led to a hierarchical relationship among all living organisms. Thus, species are categorized using a taxonomic hierarchy, starting with the binomial species name (e.g., *Homo sapiens*), moving up to genus (*Homo*), then family (*Hominidae*), and on up to Domain (*Eukarya*). Although taxonomic classifications are human constructs created to understand the real phylogeny of life\(^1\), they are nonetheless essential to organize the vast diversity of organisms. Biologists, whether studying organisms at the cell, organismal, or community level, can put their study objects into taxonomic context, allowing them to infer close and distant relatives, find relevant literature, and more.

The use of taxonomic names is, unfortunately, not straightforward. Taxonomic names often vary due to name revisions at the generic or specific levels, lumping or splitting lower taxa (genera, species) among higher taxa (families), and name spelling changes. For example, a study found that a compilation of 308,000 plant observations from 51 digitized herbarium records had 22,100 unique taxon names, of which only 13,000 were accepted names\(^2^3\). In addition, there is no one authoritative source of taxonomic names for all taxa - although, there are taxon specific sources that are used by many scientists. Different sources (e.g., uBio [Universal Biological Indexer and Organizer], Tropicos, ITIS [Integrated Taxonomic Information Service]) may use different accepted names for the same taxon. For example, while ITIS has *Helianthus x glaucus* as an accepted name, The Plant List (http://www.theplantlist.org) gives that name as unresolved. But *Helianthus glaucus* is an accepted name in The Plant List, while ITIS does not list this name.

One attempt to help inconsistencies in taxonomy is the use of numeric codes. For example, ITIS assigns a Taxonomic Serial Number (TSN) to each taxon, while uBio assigns each taxon a NameBank identifier (namebankID), and Tropicos assigns their own identifier to each taxon. Codes are helpful within a database as they can easily refer to, for example, *Helianthus annuus* with a code like 123456 instead of its whole name. However, each database uses their own code; in this case for *Helianthus annuus*, ITIS uses 36616, uBio uses 2658020, and Tropicos uses 40022652. As there are no universal codes for taxa across databases, this can lead to additional confusion. Last, name comparisons across databases have to be done with the actual names, not the codes.

Taxonomic data is getting easier to obtain through the web (e.g., http://eol.org/). However, there are a number of good reasons to obtain taxonomic information programmatically rather than through a web interface. First, if you have more than a few names to look up on a website, it can take quite a long time to enter each name, get data, and repeat for each species. Programmatically getting taxonomic names solve the problem by looping over a list of names. In addition, doing taxonomic searching, etc. becomes reproducible. With increasing reports of irreproducibility in science\(^4^5\), it is extremely important to make science workflows repeatable.

The R language is widely used by biologists, and now has over 5,000 packages on the Comprehensive R Archive Network (CRAN) to extend R. R is great for manipulating, visualizing and fitting statistical models to data. Gentleman et al.\(^6\) give a detailed discussion of advantages of R in computational biology. Getting data from the web will be increasingly common as more and more data gets moved to the cloud. Therefore, there is a need to get data from the web directly into R. Increasingly, data is available from the web via application programming interfaces (API). These allow computers to talk to one another using code that is not human readable, but is machine readable. Web APIs often define a number of methods that allow users to search for a species name, or retrieve the synonyms for a species name, for example. A further advantage of APIs is that they are language agnostic, meaning that data can be consumed in almost any computing context, allowing users to interact with the web API without having to know the details of the code. Moreover data can be accessed from every computer, whereas for example an Excel file can only be opened in a few programs.

The goal of taxize is to make many use cases that involve retrieving and resolving taxonomic names easy and reproducible. In taxize, we have written a suite of R functions that interact with many taxonomic data sources via their web APIs (Table 1). The interface to each function is usually a simple list of species names, just as a user would enter when interacting with a website. Therefore, we hope that moving from a web to an R interface for taxonomic names will be relatively seamless (if one is already nominally familiar with R).

Here, we justify the need for programmatic taxonomic resolution tools like taxize, discuss our data sources, and run through a suite of use cases to demonstrate the variety of ways that users can use taxize.

**Why do we need taxize?**

There is a large suite of applications developed around the problem of searching for, resolving, and getting higher taxonomy for species

names. For example, Linnaeus http://linnaeus.sourceforge.net/ provides the ability to search for taxonomic names in documents and normalize those names found. In addition, there are many web interfaces to search for and normalize names such as Encyclopedia of Life’s Global Names Resolver http://resolver.globalnames.org/, uBio tools http://www.ubio.org/index.php?pagename=sample_tools, and iPlant’s Taxonomic Name Resolution Service http://tnrs.iplantcollaborative.org/.

All of these data repositories provide ways to search for taxonomic names and resolve them in some cases. However, scientists ideally need a tool that is free and can be used programmatically, thereby facilitating reproducible research. The goal of taxize is to facilitate the creation of reproducible and easy to use workflows for searching for taxonomic names, resolving them, getting higher taxonomic names, and other tasks related to research dealing with species.

Data sources and package details

taxize uses many data sources (Table 1), and more can be easily added. There are two common tasks provided by the data sources: name search and name resolution. Other functionality in taxize includes retrieving a classification tree for a species, or retrieving child taxa of a focal taxon. One of the data sources (Phylomatic) returns phylogenies, while another (NCBI) returns genetic sequence data. However, there are other R packages that are focused solely on sequence data, such as rsnp⁴, rentrez⁵, BoSSA⁶, and ape⁷, so taxize does not venture deeply into these other domains.

Some of the data sources taxize interacts with require authentication. That is, in addition to the search terms the user provides (e.g., Homo sapiens), the data provider requires an alphanumeric identification key. This is necessary in some cases so that API providers can 1) better prevent databases crashing from too many requests, 2) collect analytics on requests to their API to provide better performance, etc., and 3) provide user level modification of rules for interacting with the API. The services that require an API key in taxize are: Encyclopedia of Life (EOL) http://eol.org/, the Universal Biological Indexer and Organizer (uBio) http://www.ubio.org/index.php?pagename=sample_tools, Tropicos http://www.tropicos.org/, and Plantminer⁶. One can easily obtain API keys by visiting the website of each service (see
Table 1 for links to each site). There are two typical ways of using API keys. First, you can pass in your API key in a function call (e.g., `ubio_namebank(srchName = "Ursus americanus", key = 'your_alpha-numeric_key')`). Second, you can store your key in the .Rprofile file, which is a common place to store settings. We recommend the second option as it simplifies function calls as taxize detects the stored keys.

taxize would not have been possible without the work of others. taxize uses `httr` and `RCurl` for performing calls to web APIs, XML for parsing XML, RJSONIO for parsing JSON, and `stringr` and `plyr` for manipulating data.

New data sources can be added; for example, we plan to add the following sources: Wikispecies and The Tree of Life. A connection to www.freshwaterecology.info (a database with autecological characteristics, ecological preferences, and biological traits as well as distribution patterns of more than 12,000 European freshwater organisms belonging to fish, macro-invertebrates, macrophytes, diatoms and phytoplankton) will be finished when their new API is released. In addition, the authors welcome further suggestions of data sources to be added.

Use cases

First, install taxize

First, one must install and load taxize into the R session.

```r
install.packages("taxize")
library(taxize)
```

Advanced users can also download and install the latest development copy from GitHub https://github.com/ropensci/taxize, also permanently available at http://dx.doi.org/10.5281/zenodo.7097.

Resolve taxonomic names

This is a common task in biology. We often have a list of species names and we want to know a) if we have the most up to date names, b) if our names are spelled correctly, and c) the scientific name for a common name. One way to resolve names is via the Global Names Resolver (GNR) service provided by the Encyclopedia of Life http://resolver.globalnames.org/. Here, one can search for two misspelled names:

```r
temp <- gnr_resolve(names = c("Helianthus annuus", "Homo sapiens"))
```

The correct spellings are *Helianthus annuus* and *Homo sapiens*. Another approach uses the Taxonomic Name Resolution Service via the Taxosaurus API http://taxosaurus.org/ developed by iPlant and the Phylotastic organization. In this example is a list of species names, some of which are misspelled, and then call the API with the `tnrs` function.

```r
```

It turns out there are a few corrections: e.g., *Madia sateva* should be *Madia sativa*, and *Rosa california* should be *Rosa californica*. Note that this search worked because fuzzy matching was employed to retrieve names that were close, but not exact matches. Fuzzy matching is only available for plants in the TNRS service, so we advise using EOL’s Global Names Resolver if you need to resolve animal names. taxize takes the approach that the user should be able to make decisions about what resource to trust, rather than making the decision on behalf of the user. Both the EOL GNR and the TNRS services provide data from a variety of data sources. The user may trust a specific data source, and thus may want to use the names from that data source. In the future, we may provide the ability for taxize to suggest the best match from a variety of sources.

Another common use case is when there are many synonyms for a species. In this example, there are six synonyms of the currently accepted name for a species.

```r
library(plyr)
mynames <- c("Helianthus annuus ssp. jaegeri", "Helianthus annuus ssp. lenticularis", "Helianthus annuus ssp. texanus", "Helianthus annuus var. lenticularis", "Helianthus annuus var. macrocarpus", "Helianthus annuus var. texanus")
```

### Retrieve higher taxonomic names

Another task biologists often face is getting higher taxonomic names for a taxa list. Having the higher taxonomy allows you to put into context the relationships of your species list. For example, you may find out that species A and species B are in Family C, which may lead to some interesting insight, as opposed to not knowing that Species A and B are closely related. This also makes it easy to aggregate/standardize data to a specific taxonomic level.
(e.g., family level) or to match data to other databases with different taxonomic resolution (e.g., trait databases).

A number of data sources in taxize provide the capability to retrieve higher taxonomic names, but we will highlight two of the more useful ones: Integrated Taxonomic Information System (ITIS) http://www.itis.gov/ and National Center for Biotechnology Information (NCBI)\(^1\). First, search for two species, *Abies procera* and *Pinus contorta* within ITIS.

```r
specieslist <- c("Abies procera", "Pinus contorta")
classification(specieslist, db = "ncbi")
```

<table>

<td>Abies</td>
<td>18031</td>
</tr>
<tr>
<td>Species</td>
<td>Abies procera</td>
<td>181835</td>
</tr>
</tbody>
</table>

It turns out both species are in the family Pinaceae. You can also get this type of information from the NCBI by executing the following code in R: `classification(specieslist, db = "ncbi")`.

Instead of a full classification, you may only want a single name, say a family name for your species of interest. The function `tax_name` is built just for this purpose. As with the `classification`-function you can specify the data source with the `db` argument, either ITIS or NCBI.

```r
tax_name(query = "Chironomus riparius", get = "family", db = "ncbi")
```

If a data source does not provide information on the queried species, the result could be taken from another source and the results from the different sources could be pooled.

**Interactive name selection**

As mentioned previously most databases use a numeric code to reference a species. A general workflow in taxize is: Retrieve Code for the queried species and then use this code to query more data/information. Below are a few examples. When you run these examples in R, you are presented with a command prompt asking for the row that contains the name you would like back; that output is not printed below for brevity. In this example, the search term has many matches. The function returns a data.frame of the matches, and asks for the user to input which row number to accept.

```r
get_tsn(searchterm = "Heliastes", searchtype = "sciname")
```

In another example, you can pass in a long character vector of taxonomic names:

```r
splist <- c("anonna cherimola", "anonna muricata", "quercus robur", "shorea robusta", "pandanus patina", "oryza sativa", "durio zibethinus")
get_tsn(splist, searchtype = "sciname")
```

In another example, note that no match at all returns an NA:

```r
get_uid(sciname = c("Chironomus riparius", "aaa vva"))
```

**Retrieve a phylogeny**

Ecologists are increasingly taking a phylogenetic approach to ecology, applying phylogenies to topics such as the study of community structure\(^2\), ecological networks\(^3\), and functional trait ecology\(^4\). Yet, many biologists are not adequately trained in reconstructing phylogenies. Fortunately, there are some sources for getting a phylogeny without having to know how to build one; one of these is for angiosperms, called Phylomatic\(^5\). We have created a workflow in taxize that accepts a species list, and taxize works behind the scenes to get higher taxonomic names, which are required by Phylomatic to get a phylogeny. Here is a short example, producing the tree in Figure 1.
Phylomatic has certain limitations - refer to the paper describing Phylomatic (with format "family/genus/genus_epithet"). These strings are sub-
strings is created for each species like this
nomic level, so that the data can be merged. taxize can help in this
taxonomic levels and data might have to be aggregated to a joint taxo-
Biologists often need to match different sets of data tied to spe-
Matching species tables with different taxonomic resolution

The result from the above call to col_downstream() is a data.frame
that gives a number of columns of different information.

Figure 1. A phylogeny for three species. This phylogeny was produced
using the phylomatic_tree function, which queries the Phylomatic
database, and prunes a previously created phylogeny of plants.

What taxa are children of the taxon of interest?
If someone is not a taxonomic specialist on a particular taxon they
probably do not know what children taxa are within a family, or
within a genus. This task becomes especially unwieldy when there
are a large number of taxa downstream. You can of course go to a
website like Wikispecies http://species.wikimedia.org/wiki/Main_-
Page or Encyclopedia of Life http://www.encyclopediaoflife.org/ to get downstream
names. However, taxize provides an easy way to programatically
search for downstream taxa, both for the Catalogue of Life (CoL)
http://www.catalogueoflife.org/ and the Integrated Taxonomic In-
formation System http://www.itis.gov/. Here is a short example using
the CoL in which we want to find all the species within the
genus Apis (honey bees).

IUCN status
There are a number of things a user can do once they have the cor-
rect taxonomic names. One thing a user can do is ask about the con-
servation status of a species (IUCN Red List of Threatened Species
http://www.iucnredlist.org). We have provided a set of functions,
iucn_summary and iucn_status, to search for species names, and
extract the status information, respectively. Here, you can search for
the panther and lynx.

It turns out that the panther has a status of endangered (EN) and the
lynx has a status of least concern (LC).

Search for available genes in GenBank
Another use case available in taxize deals with genetic sequences.
taxize has three functions to interact with GenBank to search for
available genes (get_genes_avail), download genes by GenBank ID
(get_genes), and download genes via taxonomic name search, in-
cluding retrieving a congeneric if the searched taxon does not exist
in the database (get_segs). In this example, one can search for gene
sequences for Umbra limi.

Then one can ask if ‘RAG1’ exists in any of the gene names.

It turns out that there are 430 different unique records found.
However, this doesn’t mean that there are 430 different genes
found as the API does not provide metadata to classify genes. You
can use regular expressions (e.g., grep) to search for the gene of
interest.

Matching species tables with different taxonomic resolution
Biologists often need to match different sets of data tied to spe-
cies. For example, trait-based approaches are a promising tool in
ecology\textsuperscript{2}. One problem is that abundance data must be matched
with trait databases such as the NCBI Taxonomy database\textsuperscript{3}. These
two data tables may contain species information on different taxo-
nomic levels and data might have to be aggregated to a joint taxo-
nomic level, so that the data can be merged. taxize can help in this
data-cleaning step, providing a reproducible workflow.

A user can use the mentioned classification-function to retrieve the
taxonomic hierarchy and then search the hierarchies up- and down-

\textbf{Abies procera}

\textbf{Helianthus annuus}

\textbf{Poa annua}
wards for matches. Here is an example to match a species (A) with names of on different taxonomic levels (B1 & B2).

```r
A <- "gammarus roeseli"
B1 <- "gammarus"
B2 <- "gammarus"
A_clas <- classification(A, db = 'ncbi')
B1_clas <- classification(B1, db = 'ncbi')
B2_clas <- classification(B2, db = 'ncbi')
A_clas[[1]]$Rank %in% B1
  # [1] "genus"
A_clas[[1]]$Rank %in% B2
  # [1] "family"
```

If one finds a direct match (here *Gammarus roeseli*), they will be lucky. However, Gammaridae can also be matched with *Gammarus roeseli*, but on a lower taxonomic level. A more comprehensive and realistic example (matching a trait table with an abundance table) is given in Appendix B.

### Aggregating data to a specific taxonomic rank

In biology, one can ask questions at varying taxonomic levels. This use case is easily handled in taxize. A function called `tax_agg` will aggregate community data to a specific taxonomic level. In this example, one can take the data for three species and aggregate them to family level. Again one can specify whether they want to use data from ITIS or NCBI. The rows in the `data.frame` are different communities.

```r
data(dune, package = 'vegan')
df <- dune[, c(1,3:4)]
colnames(df) <- c("Bellis perennis", "Juncus bufonius", "Juncus articulatus")
head(df)
# # Bellis perennis Juncus bufonius Juncus articulatus
# # 2 3 0 0
# # 13 0 3 0
# # 4 2 0 0
# # 16 0 0 3
# # 6 0 0 0
# # 1 0 0 0
```

The two *Juncus* species are aggregated to the family Juncaceae and their abundances are summed. There was only a single species in the family Asteraceae, so the data for *Bellis perennis* are carried over.

### Conclusions

Taxonomic information is increasingly sought by biologists as we take phylogenetic and taxonomic approaches to science. Taxonomic data are becoming more widely available on the web, yet scientists require programmatic access to this data for developing reproducible workflows. Taxize was created to bridge this gap - to bring taxonomic data on the web into R, where the data can be easily manipulated, visualized, and analyzed in a reproducible workflow.

We have outlined a suite of use cases in taxize that will likely fit real use cases for many biologists. Of course we have not thought of all possible use cases, so we hope that the biology community can give us feedback on what use cases they want to see available in taxize. One thing we could change in the future is to make functions that fit use cases, and then allow users to select the data source as a parameter in the function. This could possibly make the user interface easier to understand.

Taxize is currently under development and will be for some time given the large number of data sources knitted together in the package, and the fact that APIs for each data source can change, requiring changes in taxize code. Contributions to taxize are strongly encouraged, and can be easily done using GitHub here [https://github.com/ropensci/taxize](https://github.com/ropensci/taxize). We hope taxize will be taken up by the community and developed collaboratively, making it progressively better through time as new use cases arise, bug reports are squashed, and contributions are merged.

### Author contributions

SC and ES equally contributed to the software discussed in this paper, and contributed equally to writing of the manuscript.

### Competing interests

No competing interests were disclosed.

### Grant information

The author(s) declared that no grants were involved in supporting this work.
Acknowledgements
The taxize package is part of the rOpenSci project http://ropensci.org/. We thank Carl Boettiger, Karthik Ram, Owen Jones, Naim Matasci, and Ralf Schäfer for comments on previous versions of this manuscript. We thank all API maintainers for their work making their databases open to the public.

APPENDIX A. A COMPLETE REPRODUCIBLE WORKFLOW, FROM A SPECIES LIST TO A PHYLOGENY, AND DISTRIBUTION MAP.

If you aren’t familiar with a complete workflow in R, it may be difficult to visualize the process. In R, everything is programmatic, so the whole workflow can be in one place, and be repeated whenever necessary. The following is a workflow for taxize, going from a species list to a phylogeny.

First, install taxize

```r
install.packages("taxize")
```

Then load it into R

```r
library(taxize)
```

Most of us will start out with a species list, something like the one below. Note that each of the names is spelled incorrectly.

```r
```

There are many ways to resolve taxonomic names in taxize. Of course, the ideal name resolver will do the work behind the scenes for you so that you don’t have to do things like fuzzy matching. There are a few services in taxize like this we can choose from: the Global Names Resolver service from EOL (see function `gnr_resolve`) and the Taxonomic Name Resolution Service from iPlant (see function `tnrs`). In this case let’s use the function `tnrs`.

```r
# The tnrs function accepts a vector of 1 or more
splist_tnrs <- tnrs(query = splist

# Remove some fields
(splist_tnrs <- splist_tnrs[, !names(splist_tnrs) %in% c("matchedName", "annotations", "uri")])
```

There are many ways to resolve taxonomic names in taxize. Of course, the ideal name resolver will do the work behind the scenes for you so that you don’t have to do things like fuzzy matching. There are a few services in taxize like this we can choose from: the Global Names Resolver service from EOL (see function `gnr_resolve`) and the Taxonomic Name Resolution Service from iPlant (see function `tnrs`). In this case let’s use the function `tnrs`.

```r
# The tnrs function accepts a vector of 1 or more
splist_tnrs <- tnrs(query = splist

# Remove some fields
(splist_tnrs <- splist_tnrs[, !names(splist_tnrs) %in% c("matchedName", "annotations", "uri")])
```

Another thing we may want to do is collect common names for our taxa.

```r
tsns <- get_tsn(searchterm = splist, searchtype = "sciname", verbose = FALSE)
comnames <- sapply(tsns, getcommonnamesfromtsn)
```

Another thing we may want to do is collect common names for our taxa.

```r
tsns <- get_tsn(searchterm = splist, searchtype = "sciname", verbose = FALSE)
comnames <- sapply(tsns, getcommonnamesfromtsn)
```

```r
# Unfortunately, common names are not standardized like species names, so
# there are multiple common names for each taxon
sapply(comnames, length)
```
So let's just take the first common name for each species

```
comnames_vec <- do.call(c.lapply(comnames, function(x) as.character(x[1, "comname"])))
```

And we can make a data.frame of our scientific and common names

```
allnames <- data.frame(spname = splist, comname = comnames_vec)
```

<table>
<thead>
<tr>
<th>spname</th>
<th>comname</th>
</tr>
</thead>
<tbody>
<tr>
<td>Helianthus annuus</td>
<td>common sunflower</td>
</tr>
<tr>
<td>Pinus contorta</td>
<td>lodgepole pine</td>
</tr>
<tr>
<td>Collomia grandiflora</td>
<td>largeflowered collomia</td>
</tr>
<tr>
<td>Rosa californica</td>
<td>California wildrose</td>
</tr>
<tr>
<td>Mimulus bicolor</td>
<td>yellow and white monkeyflower</td>
</tr>
<tr>
<td>Nicotiana glauca</td>
<td>tree tobacco</td>
</tr>
<tr>
<td>Madia sativa</td>
<td>coast tarweed</td>
</tr>
</tbody>
</table>

Another common task is getting the taxonomic tree upstream from your study taxa. We often know what family or order our taxa are in, but it we often don’t know the tribes, subclasses, and superfamilies. taxize provides many avenues to getting classifications. Two of them are accessible via a single function (`classification`): the Integrated Taxonomic Information System (ITIS) and National Center for Biotechnology Information (NCBI); and via the Catalogue of Life (see function `col_classification`):

```
# As we already have Taxonomic Serial Numbers from ITIS, let's just get
# classifications from ITIS. Note that we could use uBio instead.
class_list <- classification(tsns)
sapply(class_list, nrow)
```

| [1] | 12 11 12 12 12 12 12 |

And we can attach these names to our allnames data.frame

```
library(plyr)
gethiernames <- function(x) {
temp <- x[, c("rankName", "taxonName")]
values <- data.frame(t(temp[, 2]))
names(values) <- temp[, 1]
return(values)
}
class_df <- ldply(class_list, gethiernames)
allnames_df <- merge(allnames, class_df, by.x = "spname", by.y = "Species")
```

<table>
<thead>
<tr>
<th>spname</th>
<th>comname</th>
<th>Kingdom</th>
<th>Subkingdom</th>
</tr>
</thead>
<tbody>
<tr>
<td>Collomia grandiflora</td>
<td>largeflowered collomia</td>
<td>Plantae Viridaeplantae</td>
<td></td>
</tr>
<tr>
<td>Helianthus annuus</td>
<td>common sunflower</td>
<td>Plantae Viridaeplantae</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Infrakingdom</td>
<td>Division Subdivision Infradivision Class</td>
</tr>
<tr>
<td>Streptophyta Tracheophyta Spermatophytina</td>
<td>Angiospermae Magnoliopsida</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Streptophyta Tracheophyta Spermatophytina</td>
<td>Angiospermae Magnoliopsida</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Superorder</td>
<td>Order</td>
<td>Family</td>
<td>Genus</td>
</tr>
<tr>
<td>Asteranae</td>
<td>Ericales</td>
<td>Polemoniaceae</td>
<td>Collomia</td>
</tr>
<tr>
<td>Asteranae</td>
<td>Asterales</td>
<td>Asteraceae</td>
<td>Helianthus</td>
</tr>
</tbody>
</table>

Ah, so Abies and Bartlettia are in different infradivisions, but share taxonomic names above that point.

However, taxonomy can only get you so far. Shared ancestry can be reconstructed from molecular data, and phylogenies created. Phylomatic is a web service with an API that we can use to get a phylogeny.
# Fetch phylogeny from phylomatic

```r
going <- phylomatic_tree(taxa = as.character(allnames$spname), taxnames = TRUE,
    get = "POST", informat = "newick", method = "phylomatic", storedtree = "R20120829",
    taxnames = "slashpath", outformat = "newick", clean = "true", parallel = TRUE)
```

# Format teeth-labels

```r
phylogeny$tip.label <- capwords(phylogeny$tip.label, onlyfirst = TRUE)
```

# plot phylogeny

```r
plot(phylogeny)
```

Using the species list, with the corrected names, we can now search for occurrence data. The Global Biodiversity Information Facility (GBIF) has the largest collection of records data, and has a API that we can interact with programmatically from R. First, we need to install rgbif.

### Install rgbif from github.com

```r
install.packages("devtools")
library(devtools)
install_github("rgbif", "ropensci")
```

Now we can search for occurrences for our species list and make a map.

```r
library(rgbif)
library(ggplot2)
# get occurrences
occurr_list <- occurrencelist_many(as.character(allnames$spname), coordinatestatus = TRUE,
    maxresults = 100, removeZeros = TRUE, fixnames = "changealltorig")
# Make a map
p <- gbifmap_list(occurr_list) + guides(col = guide_legend(title = "", nrow = 3,
    byrow = TRUE)) + theme(legend.position = "bottom", legend.key = element_blank()) +
```

**Figure A.1.** A phylogeny.
Figure A.2. A map.
APPENDIX B. MATCHING SPECIES TABLES WITH DIFFERENT TAXONOMIC RESOLUTION

Trait-based approaches are a promising tool in ecology. Unlike taxonomy-based methods, traits may not be constrained to biogeographic boundaries and have potential to disentangle the effects of multiple stressors.

To analyse trait-composition abundance data must be matched with trait databases like. However these two datatables may contain species information on different taxonomic levels and perhaps data must be aggregated to a joint taxonomic level.

taxize can help in this data-cleaning step, providing a reproducible workflow. Here we illustrate this on a small fictitious example.

Suppose we have fuzzy coded trait table with 2 traits with 3 respectively 2 modalities:

```r
(trait <- read.table(header = TRUE, sep = ';', stringsAsFactors=FALSE,
                   text = 'taxon T1M1 T1M2 T1M3 T2M1 T2M2
1 Gammarus sp. 0 0 3 1 3
2 Potamopyrgus antipodarum 1 0 3 1 3
3 Coenagrion sp. 3 0 1 3 1
4 Enallagma cyathigerum 0 3 1 0 3
5 Erythromma sp. 0 0 3 3 1
6 Baetis sp. 0 0 0 0 0')
```

And want to match this to a table with abundances:

```r
(abundances <- read.table(header = TRUE, sep = ';', stringsAsFactors=FALSE,
                         text = 'taxon abundance sample
1 Gammarus roeseli 5 1
2 Gammarus roeseli 6 2
3 Gammarus tigrinus 7 1
4 Gammarus tigrinus 8 2
5 Coenagrionidae 10 1
6 Coenagrionidae 6 2
7 Potamopyrgus antipodarum 10 1
8 xxxxx 10 2')
```

First we do some basic data-cleaning and create a lookup-table, that will link taxa in trait table with the abundance table.

```r
# first we remove ' sp.' from our trait table:
traits$taxon_cleaned <- tolower(gsub(" sp.", ",", traits$taxon))
```
# since abundance tables can be very long with repeating taxa, we look only
# at unique taxon names This will be a lookup-table linking taxon names
# between both tables
lookup <- data.frame(taxon = tolower(unique(abundances$taxon)), stringsAsFactors = FALSE)

The we query the taxonomic hierarchy for both tables, this will be the backbone of this procedure:

```r
library(taxize)
traits_classi <- classification(get_uid(traits$taxon_cleaned))
lookup_classi <- classification(get_uid(lookup$taxon))
```

First we look if we can find any direct matches between taxon names:

```r
# first search for direct matches
direct <- match(lookup$taxon, traits$taxon_cleaned)
# and add the matched name to our lookup table
lookup$traits <- tolower(traits$taxon[direct])
lookup$match <- ifelse(!is.na(direct), "direct", NA)
```

<table>
<thead>
<tr>
<th>taxon</th>
<th>traits</th>
<th>match</th>
</tr>
</thead>
<tbody>
<tr>
<td>1  gammarus roeseli</td>
<td>&lt;NA&gt;</td>
<td>&lt;NA&gt;</td>
</tr>
<tr>
<td>2  gammarus tigrinus</td>
<td>&lt;NA&gt;</td>
<td>&lt;NA&gt;</td>
</tr>
<tr>
<td>3  coenagrionidae</td>
<td>&lt;NA&gt;</td>
<td>&lt;NA&gt;</td>
</tr>
<tr>
<td>4  potamopyrgus antipodarum</td>
<td>potamopyrgus antipodarum</td>
<td>direct</td>
</tr>
<tr>
<td>5  xxxxx</td>
<td>&lt;NA&gt;</td>
<td>&lt;NA&gt;</td>
</tr>
</tbody>
</table>

We found a direct match - `potamopyrgus antipodarum` - so nothing to do here.

Next we look for species which are on a higher taxonomic resolution than our trait table. For these species we will take directly the trait-data since no better information is available.

```r
# look for cases where taxonomic resolution in abundance data is higher than
# in trait data: here we take the trait-values for the lower resolution
for (i in which(is.na(lookup$traits))) {
  if (is.data.frame(lookup_classi[[i]])) {
    matches <- tolower(lookup_classi[[i]]$ScientificName) %in% traits$taxon_cleaned
    if (any(matches)) {
      lookup$traits[i] <- tolower(lookup_classi[[i]]$ScientificName[matches])
      lookup$match[i] <- lookup_classi[[i]]$Rank[matches]
    }
  }
}
```

<table>
<thead>
<tr>
<th>taxon</th>
<th>traits</th>
<th>match</th>
</tr>
</thead>
<tbody>
<tr>
<td>1  gammarus roeseli</td>
<td>gammarus genus</td>
<td></td>
</tr>
<tr>
<td>2  gammarus tigrinus</td>
<td>gammarus genus</td>
<td></td>
</tr>
<tr>
<td>3  coenagrionidae</td>
<td>&lt;NA&gt;</td>
<td>&lt;NA&gt;</td>
</tr>
<tr>
<td>4  potamopyrgus antipodarum</td>
<td>potamopyrgus antipodarum</td>
<td>direct</td>
</tr>
<tr>
<td>5  xxxxx</td>
<td>&lt;NA&gt;</td>
<td>&lt;NA&gt;</td>
</tr>
</tbody>
</table>

So our abundance data has two *Gammarus* species, however trait data is only on genus level.

The next step is to search for species were we have to aggregate trait-data, since our abundance data is on a lower taxonomic level. We are walking the taxonomic latter for the species in our trait-data upwards and search for matches with out abundance data. Since we’ll have many taxa in the trait-data belonging to one taxon, we’ll take the median modality scores as an approximation. Of course also other methods may be used here, e.g. weighting by genetic distance.
look for cases taxonomic resolution in abundance data is lower than in trait data, here we need to aggregate the trait-values (eg. median value for modality)

```r
for (i in which(is.na(lookup$traits))) {
  # find matches
  agg <- sapply(traits_classi, function(x) any(tolower(x$ScientificName) %in% lookup$taxon[i]))
  if (sum(agg) > 1) {
    # add taxon as aggregate to trait-table
    traits <- rbind(traits, c(paste0(lookup$taxon[i], "-aggregated"), apply(traits[agg, 2:6], 2, median), paste0(lookup$taxon[i], "-aggregated")))
    # fill lookup table
    lookup$traits[i] <- paste0(lookup$taxon[i], "-aggregated")
    lookup$match[i] <- "aggregated"
  }
}
lookup
```

Finally we have only one taxon left - clearly an error. We remove this from our dataset:

```r
abundances <- abundances[!abundances$taxon == lookup$taxon[is.na(lookup$traits)],]
```

Now we can create species x sites and traits x species matrices, which could be plugged into methods to analyse trait responses.

```r
# species (as matched with trait table) by site matrix
abundances$traits_taxa <- lookup$traits[match(tolower(abundances$taxon), lookup$taxon)]
library(reshape2)
# reshape data to long format and name rows by samples
L <- dcast(abundances, sample ~ traits_taxa, fun.aggregate = sum, value.var = "abundance")
rownames(L) <- L$sample
L$sample <- NULL
L
# traits by species matrix
Q <- traits[, 2:7][match(names(L), traits$taxon_cleaned),]
rownames(Q) <- Q$taxon_cleaned
Q$taxon_cleaned <- NULL
Q
```

```r
all(rownames(Q) == colnames(L))
```

# [1] TRUE
This is just an example how taxonomic APIs (via taxize) could be used to search for matches up- and downwards the taxonomic ladder. We are looking forward to integrate the freshwaterecology.info database [www.freshwaterecology.info](www.freshwaterecology.info) into taxize, which will facilitate trait-based analyses in R.
APPENDIX C. INSTALLATION OF THE DEVELOPMENT VERSION OF TAXIZE AND API KEYS

Installing and using the development version of taxize

Stable versions of taxize are available on the Comprehensive R Archive Network (CRAN) by the following process:

```
install.packages("taxize")
library(taxize)
```

Development versions of taxize are available at Github at this link https://github.com/ropensci/taxize_, where the code-base is actively developed. This is also a good place to report bugs, submit feature requests, etc. on the Issues page https://github.com/ropensci/taxize_/issues.

The process of installing is a little bit more involved than from CRAN, but still quite easy using the package devtools http://cran.r-project.org/web/packages/devtools/index.html. If you don’t have it yet, you can install it from CRAN:

```
install.packages("devtools")
```

You also need to install development tools if you haven’t already:

- On Windows, download and install Rtools: http://cran.r-project.org/bin/windows/Rtools/. This is not an R package.
- On Mac, make sure you have either XCode (free, available in the app store) or the “Command Line Tools for Xcode” (needs a free apple id, available from http://developer.apple.com/downloads

You can check you have everything installed and working by running this code:

```
library(devtools)
has_devel()
```

Which should return ‘TRUE’. Once that is taken care of, install taxize from Github.

```
install_github("taxize_", "ropensci")
```

Then load taxize into R.

```
library(taxize)
```

See an introduction to devtools here http://adv-r.had.co.nz/Philosophy.html.

API keys

Some of the data sources we provide access to in taxize require authentication through API (Application Programming Interface) keys. Navigate to your .Rprofile file, which should be

```
open .Rprofile
```

Then write in your API key to that file and save. Let’s say we are writing a key for uBio. Put an entry in your .Rprofile file with a key of uBioApi and a value of your API key in quotes. You’ll also need to restart R after you save your .Rprofile file.

```
# uBio API key
options(uBioApi = "youralphanumerickey")
```
When you use the taxize package, the function `ubio_namebank()` will look for that key and use it in the API call. If the key is not found in your .Rprofile file the function will fail and tell you the key could not be found.

Alternatively, you can pass in the key in the function call like `ubio_namebank(searchName = 'elephant', sci = 1, vern = 0, keyCode=yourapikey)`

Functions in taxize that require API keys look for key values like `uBioApi` in your .Rprofile file. Therefore, unless you are passing your API key in the function call, save your keys in your .Rprofile file with the following key names (and their associated function names):

- **uBio**: `ubio_namebank`
- **EOLApi**: `eol_dataobjects, eol_hierarchy, eol_pages, eol_ping, eol_search`
- **tropicoskey**: `tp_acceptednames, tp_namendistributions, tp_nameeferences, tp_summary, tp_synonyms`
- **pmkey**: `plantminer`

Gavin L. Simpson
Department of Biology, University of Regina, Regina, SK, Canada

The author's have addressed my comments on the original version of their manuscript. The issues I pointed to regarding naming conventions were not intended to be addressed now but in a future version of the package. The new appendix is a good addition to the manuscript, although I don't fully follow why "open .Rprofile" is highlighted as code?

Competing Interests: No competing interests were disclosed.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

Author Response 05 Nov 2013
Scott Chamberlain, Simon Fraser University, Burnaby, Canada

Thanks for the feedback Gavin. Good point that the line "open .Rprofile" should not be highlighted as code. I will see if we can fix that. - Scott

Competing Interests: No competing interests were disclosed.

Reviewer Report 29 October 2013

Will Pearse
College of Biological Sciences, University of Minnesota, Minneapolis, MN, USA

The authors have addressed all my concerns, and I think it's perfectly reasonable to address naming conventions in the next release of the package. The third appendix is a particularly nice addition; if the authors intend to alter the manuscript when they next update the package, the section entitled 'API Keys' may contain a minor typo/area that's not perfectly clear (see below) but I was still able to follow the appendix to alter my .Rprofile.

"Navigate to your .Rprofile file, which should be open .Rprofile"

Ethan White

Department of Biology, Utah State University, Logan, UT, USA

This software paper describes an R package that provides an integrated R interface for the APIs of over a dozen taxonomically related web services. This is a valuable contribution because it will save researchers time and energy (for those capable of wrapping the APIs themselves), and will allow scientists who lack the technical knowledge to interact with web services themselves to use this data from R. In addition, some of the functions combine existing APIs in useful ways.

The software was developed using version control, on a public development site (https://github.com/ropensci/taxize_), and using a bug tracker. The code is well modularized and includes an extensive test suite. This level of good software practice is notable for scientific software and is indicative of well built and maintained code. It also has a clearly declared CC0 license making it easy for others to use and build on the software.

The software installed easily in R using the standard approach and generally works as expected based on the examples in the paper and on the project's website.

My one major suggestion is to reinforce what the authors’ have already suggested in the Conclusions, that it would be an improvement to move to a design that focuses on having a single top-level function for each type of task that the library handles with different data sources being selected using a parameter. This would allow the users to benefit maximally from one of the stronger aspects of this library, which is that it combines access to large numbers of data sources, by making it more of an integrated system and less of a collected set of API wrappers.

Minor issues:

1. The code snippets are images rather than text. This is probably a limitation of the publishing platform, but it does make it more difficult to learn about the software by executing the code snippets.

2. The following two sentences seem rather tangential to the paper and could be removed:
   “Science workflows can now easily incorporate text, code, and images in a single executable
2. Reproducible documents should become mainstream in biology to avoid mistakes, and make collaboration easier."

3. Given that many of the target users of this package will not be particularly familiar with web services and APIs, I would recommend adding another sentence or two to the paragraph on authentication so that readers understand why this is required (i.e., most readers won't understand "users that abuse the API") and what it really is (i.e., an individual login of sorts, similar to a username/password).

4. The section on "Aggregating data to a specific taxonomic rank" refers to an example, but none appears to be present.

**Competing Interests:** No competing interests were disclosed.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

---

**Author Response 14 Oct 2013**

**Scott Chamberlain**, Simon Fraser University, Burnaby, Canada

We appreciate Dr. White's comments on our manuscript.

We removed the sentences "Science workflows can now easily incorporate text, code, and images in a single executable document. Reproducible documents should become mainstream in biology to avoid mistakes, and make collaboration easier."

In response to this reviewer's comment about clarification on APIs and authentication, and Dr. Pearse's comments on the same issue, we have added a new appendix (Appendix C) that explains how to use API keys and install the development version of taxize.

This reviewer commented that the section on Aggregating data to a specific taxonomic rank referred to an example, but none appeared to be present. The example is now in the paper.

**Competing Interests:** No competing interests were disclosed.
Chamberlain and Szöcs present the taxize R package, a set of functions that provides interfaces to several web tools and databases, and simplifies the process of checking, updating, correcting and manipulating taxon names for researchers working with ecological/biological data. A key feature that is repeated throughout is the need for reproducibility of science workflows and taxize provides a means to achieve this within the R software ecosystem for taxonomic search.

The manuscript is well-written and nicely presented, with a good balance of descriptive text and discourse and practical illustration of package usage. A number of examples illustrate the scope of the package, something that is fully expanded upon in the two appendices, which are a welcome addition to the paper.

As to the package, I am not overly fond of long function names; the authors should consider dropping the data source abbreviations from the function names in a future update/revision of the package. Likewise there is some inconsistency in the naming conventions used. For example there is the 'tpl_search()' function to search The Plant List, but the equivalent function to search uBio is 'ubio_namebank()'. Whilst this may reflect specific aspects of terminology in use at the respective data stores, it does not help the user gain familiarity with the package by having them remember inconsistent function names.

One advantage of taxize is that it draws together a rich selection of data stores to query. A further suggestion for a future update would be to add generic function names, that apply to a database connection/information object. The latter would describe the resource the user wants to search and any other required information, such as the API key, etc., for example:

```r
foo <- taxizeDB(what = "uBio", key = "1646546164694")
```

The user function to search would then be 'search(foo, "Abies")'. Similar generically named functions would provide the primary user-interface, thus promoting a more consistent toolbox at the R level. This will become increasingly relevant as the scope of taxize increases through the addition of new data stores that the package can access.

In terms of presentation in the paper, I really don't like the way the R code inputs merge with the R outputs. I know the author of Knitr doesn't like the demarcation of output being polluted by the R prompt, but I do find it difficult parsing the inputs/outputs you show because often there is no space between them and users not familiar with R will have greater difficulties than I. Consider adding in more conventional indications of R outputs, or physically separate input from output by breaking up the chunks of code to have whitespace between the grey-background chunks. Related, in one location I noticed something amiss with the layout; in the first code block at the top of page 5, the printed output looks wrong here. I would expect the attributes to print on their own line and the data in the attribute to also be on its own separate line.

Note also, the inconsistency in the naming of the output object columns. For example, in the two code chunks shown in column 1 of page 4, the first block has an object printed with column names 'matched_name' and 'data_source_title', whilst camelCase is used in the outputs shown in the second block. As the package is revised and developed, consider this and other aspects of providing a consistent presentation to the user.

I was a little confused about the example in the section Resolve Taxonomic Names on page 4. Should the taxon name be "Helianthus annuus" or "Helianthus annus"? In the 'mynamen' definition you include 'Helianthus annuus' in the character vector but the output shown suggests that the submitted name was 'Helianthus annus' (1 "u") in rows with rownames 9 and 10 in the output shown.
Other than that there were the following minor observations:

1. Abstract: replace "easy" with "simple" in "...fashion that's easy...", and move the details about availability and the URI to the end of the sentence.
2. Page 2, Column 1, Paragraph 2: You have "In addition, there is no one authoritative taxonomic names source...", which is a little clumsy to read. How about "In addition, there is no one authoritative source of taxonomic names..."?
3. Pg 2, C1, P2-3: The abbreviated data sources are presented first (in paragraph 2) and subsequently defined (in para 3). Restructure this so that the abbreviated forms are explained upon first usage.
4. Pg 2, C2, P2: Most R packages are "in development" so I would drop the qualifier and reword the opening sentence of the paragraph.
5. Pg 2, C2, P6: Change "and more can easily be added" to "and more can be easily added" seems to flow better?
6. Pg 5, paragraph above Figure 1: You refer to converting the object to an **ape** *phylo* object and then repeat essentially the same information in the next sentence. Remove the repetition.
7. Pg 6, C1: The header may be better as "Which taxa are children of the taxon of interest".
8. Pg 6: In the section "IUCN status", the term "we" is used to refer to both the authors and the user. This is confusing. Reserve "we" for reference to the authors and use something else ("a user" perhaps) for the other instances. Check this throughout the entire manuscript.
9. Pg 6, C2: in the paragraph immediately below the 'grep()' for "RAG1", two consecutive sentences begin with "However".
10. Pg 7: The first sentence of "Aggregating data...." reads "In biology, one can asks questions...". It should be "one asks" or "one can ask".
11. Pg 7, Conclusions: The first sentence reads "information is increasingly sought out by biologists". I would drop "out" as "sought" is sufficient on its own.
12. Appendices: Should the two figures in the Appendices have a different reference to differentiate them from Figure 1 in the main body of the paper? As it stands, the paper has two Figure 1s, one on page 5 and a second on page 12 in the Appendix.
13. On Appendix Figure 2: The individual points are a little large. Consider reducing the plotting character size. I appreciate the effect you were going for with the transparency indicating density of observation through overplotting, but the effect is weakened by the size of the individual points.
14. Should the phylogenetic trees have some scale to them? I presume the height of the stems is an indication of phylogenetic distance but the figure is hard to calibrate without an associated scale. A quick look at Paradis (2012) Analysis of Phylogenetics and Evolution with R would suggest however that a scale is not consistently applied to these trees. I am happy to be guided by the authors as they will be more familiar with the conventions than I.

**Competing Interests:** No competing interests were disclosed.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.
- ...there is some inconsistency in the naming conventions used. For example there is the 'tpl_search()' function to search The Plant List, but the equivalent function to search uBio is 'ubio_namebank()'. Whilst this may reflect specific aspects of terminology in use at the respective data stores, it does not help the user gain familiarity with the package by having them remember inconsistent function names.

We agree that we should definitely improve naming conventions for functions. However, we think it's better to change the function names as needed in an upcoming version of the software after we have had time work on the problem.

- Consider adding in more conventional indications of R outputs, or physically separate input from output by breaking up the chunks of code to have whitespace between the grey-background chunks.

We have used comments (pound signs) for the results of function calls within each code block to indicate output as separate from code input. This way users can copy/paste code directly into R to try it out.

- in one location I noticed something amiss with the layout; in the first code block at the top of page 5, the printed output looks wrong here. I would expect the attributes to print on their own line and the data in the attribute to also be on its own separate line.

This was a problem with the typesetting, and we have fixed it.

- the inconsistency in the naming of the output object columns. For example, in the two code chunks shown in column 1 of page 4, the first block has an object printed with column names 'matched_name' and 'data_source_title', whilst camelCase is used in the outputs shown in the second block.

We agree that we should definitely improve naming conventions for object columns. However, we think it's better to change the column names as needed in an upcoming version of the software after we have had time work on the problem.

- I was a little confused about the example in the section Resolve Taxonomic Names on page 4. Should the taxon name be "Helianthus annuus" or "Helianthus annus"? In the 'mynames' definition you include 'Helianthus annuus' in the character vector but the output shown suggests that the submitted name was 'Helianthus annuus' (1 "u") in rows with rownames 9 and 10 in the output shown.

Fixed.

- Abstract: replace "easy" with "simple" in "...fashion that's easy...", and move the details about availability and the URI to the end of the sentence.

Fixed.

- Page 2, Column 1, Paragraph 2: You have “In addition, there is no one authoritative taxonomic names source...”, which is a little clumsy to read. How about "In addition, there is no one authoritative source of taxonomic names..."?
Changed.

- Pg 2, C1, P2-3: The abbreviated data sources are presented first (in paragraph 2) and subsequently defined (in para 3). Restructure this so that the abbreviated forms are explained upon first usage.

Changed.

- Pg 2, C2, P2: Most R packages are "in development" so I would drop the qualifier and reword the opening sentence of the paragraph.

Changed.

- Pg 2, C2, P6: Change "and more can easily be added" to "and more can be easily added" seems to flow better?

Changed.

- Pg 5, paragraph above Figure 1: You refer to converting the object to an ape phylo object and then repeat essentially the same information in the next sentence. Remove the repetition.

Removed.

- Pg 6, C1: The header may be better as "Which taxa are children of the taxon of interest".

Changed.

- Pg 6: In the section "IUCN status", the term "we" is used to refer to both the authors and the user. This is confusing. Reserve "we" for reference to the authors and use something else ("a user" perhaps) for the other instances. Check this throughout the entire manuscript.

Fixed.

- Pg 6, C2: in the paragraph immediately below the `grep()` for "RAG1", two consecutive sentences begin with "However".

Changed.

- Pg 7: The first sentence of "Aggregating data...." reads "In biology, one can asks questions...". It should be "one asks" or "one can ask"

Changed.

- Pg 7, Conclusions: The first sentence reads "information is increasingly sought out by biologists". I would drop "out" as "sought" is sufficient on its own.

Changed.
- Appendices: Should the two figures in the Appendices have a different reference to differentiate them from Figure 1 in the main body of the paper? As it stands, the paper has two Figure 1s, one on page 5 and a second on page 12 in the Appendix.

Fixed.

- On Appendix Figure 2: The individual points are a little large. Consider reducing the plotting character size. I appreciate the effect you were going for with the transparency indicating density of observation through overplotting, but the effect is weakened by the size of the individual points.

Although we agree that the styling of the figure could be improved, we are going to leave it as is because it’s not important for understanding the material.

- Should the phylogenetic trees have some scale to them? I presume the height of the stems is an indication of phylogenetic distance but the figure is hard to calibrate without an associated scale. A quick look at Paradis (2012) Analysis of Phylogenetics and Evolution with R would suggest however that a scale is not consistently applied to these trees. I am happy to be guided by the authors as they will be more familiar with the conventions than I.

A scale could be used for sure. However, our focus is on showing readers that they can get data which can be used to make a phylogeny, not on how to properly create and display a phylogeny. Thus, we are leaving the phylogeny as is without a scale.

The software this article describes is well-written and of use to ecologists. The guide and appendices in this article give a good overview of the features of the package, and are well-written. The title and abstract are well-written.

My only serious comment would be that the authors refer to species' taxonomy as if it perfectly reflects species' phylogeny (e.g. the end of the first paragraph in the introduction and the first paragraph in the section "retrieve higher taxonomic names"). More often than not, taxonomy does reflect phylogeny, but a sentence clarifying this distinction somewhere might be helpful.

A few minor things:
- Table 1 - “National Center for Biotechnology Information Federhen” - the author's surname, but not the citation, is in the text; "searchbycommonname" and "searchbyscientificname" seem to be the only elements not in alphabetical order in the table.

- Phylomatic can now create phylogenies for mammals, not just angiosperms (e.g. "retrieve a phylogeny").

- Some sentences could perhaps be linked more neatly in the introduction (e.g. "gives that name as unresolved. But Helianthus", "moved to the cloud. Therefore there is a need", "additional confusion. Last, name"). Similarly, page 3 has some very short paragraphs; could the descriptions of taxonstand and The Plant List be moved to table 1? "Science workflows" or "scientific workflows" (fourth paragraph of introduction)? These are all very minor points!

- Perhaps an example of what to type in order to add API keys into the .Rprofile would be helpful, or maybe could just be added to the help file for "ubio_namebank" as this is the function named when it's mentioned.

**Competing Interests:** No competing interests were disclosed.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.

**Author Response 14 Oct 2013**

**Scott Chamberlain**, Simon Fraser University, Burnaby, Canada

We appreciate Dr. Pearse's comments on our manuscript. We agree that species taxonomy does not equate to phylogenetic history, so we added the following sentence to the first paragraph: "Although taxonomic classifications are human constructs created to understand the real phylogeny of life \cite{benton2000}, they are nonetheless essential to organize the vast diversity of organisms." We fixed the citation in Table 1, and reordered the functions in the table so as to be alphabetical. Thanks for pointing out that Phylomatic now accepts mammals in addition to Angiosperm plants - we have adjusted the language accordingly.

We removed the description of Taxonstand and the Plantlist.org (and associated references) that this reviewer referred to as it wasn't necessary and improves reading.

This reviewer asked for a better explanation of how to use the API keys and the .Rprofile file. In response, we have added a new appendix (Appendix C) that explains using API keys and installing the development version of taxize.
