Abstract

With less than 40 cases reported, primary leiomyosarcoma is an extremely rare form of breast cancer (less than 0.0006% of cases) with unpredictable biological behavior that usually presents as a slow growing, mobile mass in middle age women. Most cases are low-grade and are cured by complete excision with wide margins. After surgical resection, late local recurrence and distant hematogenous metastasis to lungs and liver is, however, well-documented. To the best of our knowledge, bone metastasis has never been reported. Here we present a case of primary leiomyosarcoma of the breast metastatic to the femur.
Case report
A 58 year-old woman (G4P2) with no prior mammograms presented with complaint of increasing pain in her right breast for 7 months. Physical examination revealed an enlarged breast with multiple visible nodules but no adenopathy. Mammography detected a large mass associated with calcifications and thickening of the overlying skin (BIRADS 5) (Figure 1). The left breast was normal. Sonographically, the mass was primarily hypoechoic (Figure 2). MRI with contrast showed a lobulated, heterogeneously enhancing mass involving most of the right breast with multiple areas of necrosis. No lymphadenopathy or chest wall involvement was seen (Figure 3).

Ultrasound guided core biopsy of the right breast revealed a spindle-cell neoplasm composed of tumor cells with blunt ended nuclei that were strongly positive for smooth muscle actin (SMA) and lacked expression of pan-cytokeratin, CD34, and S-100 (not shown). This immunophenotype is most consistent with a diagnosis of breast sarcoma. Metastatic workup detected small bilateral lung nodules.

In 2011 the patient underwent right total mastectomy with partial resection of the pectoralis muscle without chemo- or radiation therapy. Gross examination of the mastectomy specimen revealed a large (15 cm), firm, well-circumscribed mass. Microscopically, the tumor was composed of relatively bland spindle cells arranged as intersecting fascicles. The tumor was positive for SMA and vimentin, and negative for desmin, S-100, CD34, pan-cytokeratin, and neuron-specific enolase. A diagnosis of leiomyosarcoma was made. The resection margins were clean (> 1 cm).

Two years later, the patient returned with a deep aching pain in her right knee and lower thigh. An X-Ray of her right femur showed a large lucent lesion with endosteal scalloping, suspicious for metastatic disease (Figure 4). A repeat nuclear bone scan was positive for a new increased radiotracer uptake in the right femur. A CT of the chest, abdomen and pelvis discovered a new 3 cm soft tissue mass within the soft tissues in the right gluteal region and multiple lung nodules that were either new or have increased in size compared to previous CTs (Figure 5). An ultrasound guided right gluteal mass full-core biopsy revealed a spindle cell neoplasm similar to the previously excised breast leiomyosarcoma, confirming the diagnosis of metastatic disease (Figure 6). The metastatic gluteal and femoral tumors were resected and chemotherapy with Gemzar...
Primary leiomyosarcoma of the breast is an extremely rare malignant neoplasm of uncertain biological behavior. There are less than 40 well-documented cases reported in the English medical literature.

The majority of these cases presented as a well-circumscribed mass in the breast of postmenopausal women, although it has also been described in adolescent girls. The histogenesis of the entity is not clear. The myofibroblasts in the nipple areola complex have been proposed as the origin for the neoplasm.

Most reported cases were relatively indolent but aggressive behavior with local recurrence and distant hematogenous metastasis to lungs and liver is also well-documented. The mainstay treatment is wide margin local excision. Most reported cases have undergone mastectomy with a few exceptions being treated with lumpectomy. Axillary dissection is believed to be unnecessary as the primary leiomyosarcoma of the breast does not spread through the lymphatic route.

With a size of 15 cm, the present case represents the third largest tumor of all documented cases. Although bone is a common metastatic site for breast carcinoma, to the best of our knowledge breast leiomyosarcoma metastatic to the bone has not been reported. Prognostic factors predicting aggressive biological behavior in mammary leiomyosarcomas are yet to be established.
Consent
Written informed consent for publication of clinical details and clinical images was obtained from the patient.

Author contributions
The imaging studies were performed by Drs. Sokolovskaya and Shariff. The pathology work-up was done by Drs. Liu and Weintraub. The diagnostic pathology slides were reviewed and the manuscript was written by Dr. Szallasi. All authors were involved in critically revising the manuscript and approved the final version for publication.

Competing interests
No competing interests were disclosed.

Grant information
The author(s) declared that no grants were involved in supporting this work.

The title covers the content and the message of the manuscript. The abstract summarizes the content of the article briefly and in a way easy to understand. The abstract is well-constructed and clear. The conclusion is sensible and well-balanced. Although the authors present a case first reported in the literature the conclusion is modest. There are no bias or competing interests.

The manuscript meets the criteria for case reports of the journal.

It reports the first diagnosed case of bone metastasis of a rare disorder, the leiomyosarcoma of the breast in a well-documented and straightforward way. Reviewing the literature no English article about a case like this was found, thus, the primary rank can be confirmed. The article is valuable not only due to the description of an extremely rare case, but it also calls the attention to the possibility of bone metastasis in this disorder that should be sought for in the future in leiomyosarcoma. I fully support the indexing of the article.

Competing Interests: No competing interests were disclosed.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.
