Abstract

regionReport is an R package for generating detailed interactive reports from regions of the genome. The report includes quality-control checks, an overview of the results, an interactive table of the genomic regions and reproducibility information. regionReport can easily be expanded with report templates for other specialized analyses. In particular, regionReport has an extensive report template for exploring derfinder results from annotation-agnostic RNA-seq differential expression analyses.

Introduction

Many analyses of genomic data result in regions along the genome that associate with a covariate of interest. These genomic regions can result from identifying differentially bound peaks from ChIP-seq data, identifying differentially methylated regions (DMRs) from DNA methylation data, or performing base-resolution differential expression analyses using RNA sequencing data. The genomic regions themselves are commonly stored in a GRanges object from GenomicRanges when working with R or the BED file format on the UCSC Genome Browser, but other information on these regions, for example summary statistics on the magnitude of effects and statistical significance, also provide useful information. The usage of R in genomics is increasingly common due to the usefulness and popularity of the Bioconductor project, and in the latest version (3.0), 181 unique packages use GenomicRanges for many workflows, demonstrating the widespread utility of identifying and summarizing characteristics of genomic regions.

Here we introduce regionReport which allows users to explore genomic regions of interest through interactive stand-alone HTML reports that can be shared with collaborators. These reports are flexible enough to display plots and quality control checks within a given experiment, but can easily be expanded to include custom visualizations and conclusions. The resulting HTML report emphasizes reproducibility of analyses by including all the R code without obstructing the resulting plots and tables. We envision regionReport will provide a useful tool for exploring and sharing genomic region-based results from high throughput genomics experiments.

Methods
Implementation

The package includes a R Markdown template which is processed using knit and rmarkdown, then styled using knitrBootstrap. This package generates a HTML report that includes a series of plots for checking the quality of the results and browsing the table of regions. Each element of the report has a brief explanation, although actual interpretation of the results is dataset- and workflow-dependent. To facilitate navigation a menu is always included, which is useful for users interested in a particular section of the report. Figure 1, panel a shows the menu of the general report for a set of regions with associated p-values. The code for each plot or table is hidden by default and can be shown by clicking on the appropriate toggle as shown in Figure 2.

![Diagram](image.png)

**Figure 1. regionReport workflow.** Example region input, the appropriate regionReport function to use, and menu of the resulting report for the general use case (panel a) and derfinder results (panel b).
Quality checks
This section of the report includes a variety of quality control steps which help the user determine whether the results are sensible. The quality control steps explore:

- P-values, Q-values, and FWER adjusted p-values
- Region width
- Region area: sum of single-base level statistics (if available)
- Mean coverage or other score variables (if available)

A combination of density plots and numerical summaries are used in these quality checks. If there are statistically significant regions, the distributions are compared between all regions and the significant ones. For example, the distribution region widths might have a high density of small values for the global results, but shifted towards higher values for the subset of significant regions.

Genomic overview
The report includes plots to visualize the location of all the regions as well as the significant ones. Differences between them can reveal location biases. The nearest known annotation feature for each region is summarized and visually inspected in the report.

Best regions
An interactive table with the top 500 (default) regions is included in this section. This allows the user to sort the region information according to their preferred ranking option. For example, lowest p-value, longest width, chromosome, nearest annotation feature, etc. The table also allows the user to search and subset it interactively. A common use case is when the user wants to check if any of the regions are near a known gene of their interest.

Reproducibility
At the end of the report, detailed information is provided on how the analysis was performed. This includes the actual function call to generate the report, the path where the report was generated, time spent, and the detailed R session information including package versions of all the dependencies.

The R code for generating the plots and tables in the report is included in the report itself, thus allowing users to manually reproduce any section of the report, customize them, or simply change the graphical parameters to their liking.

**derfinder report**
When exploring derfinder results, for each of the best 100 (default) DERs a plot showing the coverage per sample is included.
in the report. These plots allow the user to visualize the differences identified by derfinder along known exons, introns and isoforms. The plots are created using derfinderPlot, also available via Bioconductor.

Due to the intrinsic variability in RNA-seq coverage data or mapping artifacts, in situations where there are two candidate DERs that are relatively close there might be reasons to consider them a single candidate DER and its important to visualize them. This tailored report groups candidate DERs into clusters based on a distance cutoff. After ranking them by their area, for the top 20 (default) clusters it plots tracks with the coverage by sample, the mean coverage by group, the identified candidate DERs colored by whether they are statistically significant, and known alternative transcripts. Figure 1, panel b shows the main categories of the report generated from a richer region data set than in the general case.

**Operation**

**Installation.** regionReport and required dependencies can be easily installed from Bioconductor with the following commands:

```r
source("http://bioconductor.org/biocLite.R")
biocLite("regionReport")
```

**Input.** To generate the report, the user first has to identify the regions of interest according to their analysis workflow. For example, by performing bumphunting to identify DMRs with bumphunter. The report is then created using renderReport() which is the main function in this package as shown in Figure 1, panel a. The argument customCode can be used to customize the report if necessary.

For the derfinder use case, the derfinderReport() function creates the recommended report that includes visualizations of the coverage information for the best regions and clusters of regions.

**Output.** A small example can be generated using:

```r
example("renderReport", "regionReport", ask=FALSE)
```

The resulting HTML file will open in the users default browser. Note that alternative output formats such as PDF files can also be generated, although they are not as dynamic and interactive as the HTML format.

**Use cases**

The supplementary website contains reports using DiffBind, bumphunter and derfinder results. The derfinder use case is illustrated with data sets previously described in 3 which span simulation results, a moderately sized data set (25 samples), and a large data set with 487 samples; thus covering a wide range of scenarios.

**Summary**

regionReport creates interactive reports from a set of regions and can be used in a wide range of genomic analyses. Reports generated with regionReport can easily be extended to include further quality checks and interpretation of the results specific to the data set under study. These shareable documents are very powerful when exploring different parameter values of an analysis workflow or applying the same method to a wide variety of data sets. The reports allow users to visually check the quality of the results, explore the properties of the genomic regions under study, and inspect the best regions and interactively explore them.

Furthermore, regionReport promotes reproducibility of data exploration and analysis. Each report provides R code that can be used as the starting point for other analyses within a dataset. regionReport provides a flexible output for exploring and sharing results from high throughput genomics experiments.

**Software availability**

**Software access**

regionReport is freely available via Bioconductor at bioconductor.org.

http://leekgroup.github.io/regionReportSupp/ hosts the code for generating three types of reports as well as the resulting HTML reports generated by regionReport. Versions of all software used are included in the reports.

**Latest source code**

The latest source code is available at Bioconductor and github.com/leekgroup/regionReport via the git-svn bridge although we recommend users to install regionReport directly from Bioconductor.

**Archived source code as at the time of publication**

Archived source code available at http://dx.doi.org/10.5281/zenodo.17083

**License**

Artistic-2.0.

**Author contributions**

L.C-T. conceived and developed the regionReport package, supervised by A.E.J. and J.T.L. All authors wrote and approved the final manuscript.

**Competing interests**

No competing interests were disclosed.

The authors present regionReport, an R package to produce interactive HTML reports from a genomic-region based analysis, such as those produced by derfinder, bumphunter or DiffBind. The report shows quality control summaries, interactive tables of the most significant regions, and information on how regions lie in exons, introns, and intergenic regions. Both novice and expert genomicists are sure to gain much from this, and the paper clearly and concisely explains the software and its use, while providing useful examples and instructions.

The idea of producing common reports for a Bioconductor object is ingenious, and will hopefully inspire packages for other types of biological data. One of the great strengths of the package is the reproducibility practices it follows. For example, the section at the end of the produced report that shows reproducibility information, such as the original command, the session info, and the amount of time the report took to generate, is a great idea. (Indeed, the option to add sessionInfo() and timers could probably be baked into rmarkdown, or a thin wrapper thereof). Another strength is the use of modern knitr templates, such as expandable tables. Scientists who want to develop automated reports should use this package as a guide.

Overall my concerns are minor, and mostly concern the package rather than the paper, some of which I attempt to address in a GitHub pull request.

In pull request
- If the renderReport function leaves early (for example, if it is interrupted by the user hitting Stop) it strands the user's R session in a working directory. Using the on.exit function, as described here, lets R return to the original directory instead.

- The options for customization of the report are limited, by the customCode argument, to chunks between the main text and the reproducibility section. Genomicists may wish to take advantage of these reports while customizing some of their outputs. (For example, the authors of region-finding packages may wish to wrap renderReport with a customized template for their own objects). I've added a template argument in my pull request, and go over another suggestion below.

Not in pull request
- The 'template' argument is a start towards greater customization, but a further improvement would be to allow the user to provide a list of customized internal chunks (for example, density-pvalue). As it is now, these are constructed in the renderReport function and cannot be altered without rewriting the entire function. This suggests finding a way to abstract them, such as bringing them in
from a separate file, would be useful.

- As one example of an important customization I'd make: the reports show density plots of p-values and q-values, but in my experience genomicists are more accustomed to histograms (especially since bumps in density plots may be misleading, while histograms can get a better sense of which bumps are meaningful). I understand if the authors wish to keep it as a density plot, but if so I would appreciate a way to change it for my own use.

**Minor issues**

- The use of "smart quotes" in code within the PDF, such as source ("http://bioconductor.org/biocLite.R"), make it inconvenient to copy and paste them into an R terminal. If there's any way this could be remedied by the author or editors, it should.

**Competing Interests:** No competing interests were disclosed.

I have read this submission. I believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard.
something to consider for future versions.

3. Reduce the number of dependencies. `locfdr` is no longer on CRAN. On a slightly slower than normal connection (currently on travel) it took a fairly long time to track down and install all the dependencies. I’d recommend moving non-essential dependencies to suggests and using something like this to selectively install packages as needed using `requireNamespace(pkg, quietly = TRUE)`. It was disappointing to go down a rabbit hole of dependencies and still not be able to install and run examples. However, I found the report examples posted online (here: http://leekgroup.github.io/regionReportSupp/bumphunter-example/index.html and here: http://leekgroup.github.io/regionReportSupp/DiffBind-example/index.html) extremely useful. The use of Twitter bootstrap also adds a layer of a familiarity that I found extremely useful.

4. It would be nice to have the package generate a direct link to the bib file under the bibliography.

**Competing Interests:** In my suggestions to improve the software, I’ve recommended adding one dependency tool on which I am a coauthor. The software itself is free and I don’t benefit from any citations (there is no paper associated with that software). In this case it would really help make it easier for researchers to publish their reports generated by the software described in this paper. It did not affect my review and I have offered that addition only as a suggestion (not a requirement to acceptance).

I have read this submission. I believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.

Needs more figures to demonstrate why a user would choose this tool. For example http://leekgroup.github.io/regionReportSupp/bumphunter-example/index.html (but even better would be to show an example, e.g. ITGB2 exon inclusion/exclusion or multiscale DMRs, where in our hands at least, nothing else short of IGV really does the job, and IGV doesn’t do it that well.) The software is a firm foundation but the writeup needs work if it is to be compelling and thus influence readers to try out an unfamiliar tools.

My apologies for being harsh, but without figures, an applied paper simply will not be read. I would be less harsh if the underlying work were not compelling enough to command broader interest. A poor writeup will doom the work to obscurity.

**Competing Interests:** No competing interests were disclosed.

I have read this submission. I believe that I have an appropriate level of expertise to state that I do not consider it to be of an acceptable scientific standard, for reasons outlined above.
Author Response 18 May 2015

**Jeffrey Leek**, Johns Hopkins Bloomberg School of Public Health, USA

Thanks, we will update with more figures and expand the description. This is meant to be a short description of the software but we certainly appreciate the feedback on how to increase users. We will update the draft and respond shortly.

**Competing Interests:** No competing interests were disclosed.
