Abstract

Introduction: The number of publications in Scopus on this topic increased from less than 50 in 1995 to more than 250 in 2015. In other hand, inconsistency in results about the correlation between yeast and lactic acid bacteria as probiotics has been evident since the early publications on use in broilers.

Methods: A meta-analysis was conducted to determine relationship between lactic acid bacteria and yeast as probiotics to broiler diets on the growth performance, relative organ weight, blood parameters, and immune response of the broiler. A database was designed based on published data that reported the use of probiotics on the broiler. The method used for selecting articles was based on the Preferred Reporting Items for Systematic Review and Meta-Analyses (PRISMA) method. Articles selected were taken from PubMed, Web of science, Scopus, Google Scholar, and Science direct databases as well as individual.

Results: The final database consists of 49 in vivo articles, 93 studies, and 225 treatments. The analysis statement in the system was a PROC MIXED procedure of SAS software. The level of probiotic increased (p <0.001) body weight, body weight gain, and feed intake of broiler. There was a reduction (p <0.01) on feed conversion ratio and mortality on the level probiotic given to broiler. Supplementation of probiotics

Any reports and responses or comments on the article can be found at the end of the article.
in broiler diet increased (p <0.001) the weight of liver, spleen, gizzard, bursa of fabricius and carcass yield, while reduced (p<0.001) abdominal fat weight. The probiotic given increased the total of red and white blood cells (both at p < 0.001) but did not affect lymphocyte.

**Discussion:** It can be concluded the yeast act as supporting agent that serves lactic acid bacteria as probiotic increases the growth performance, relative organ weight, blood parameters, and immune response of the broiler.

**Keywords**
broiler, lactic acid bacteria, meta-analysis, probiotic, yeast.
Introduction

In 1997, the use of antibiotics in livestock was first addressed in Denmark with *avoparcin* as an antibiotic growth promoter (AGP). The trend continued and a European Union (EU)-wide ban on AGPs in animal feed (poultry) took effect in 2006 (EC Regulation No 1831/2003). Since then, this type of regulation has spread to developing countries, including Indonesia, which has been banning antibiotics and imported poultry feed products since the most recent regulation, PERMENTAN/14/16/2017, was put in place. The EU introduced probiotics as an alternative to antibiotics and this has subsequently become an area of great interest for researchers worldwide. Probiotics are living microorganisms that when ingested in sufficient amounts, may positively improve growth, intestinal health and animal productivity. Probiotics are commonly sourced from lactic acid bacteria, namely, *Lactobacillus* and *Bifidobacterium*, which are usually found in the intestine.

Earlier studies have reported an active role for probiotics in reducing or eliminating the pathogen bacteria in the intestine. In recent research, probiotic mixtures have also been found to have beneficial effects against a wide range of disorders, although evidence that mixtures are more effective than their component strains is more limited. Nevertheless, in the future, a further potential advantage of multi-strain probiotics, in addition to exerting additive or synergistic effects, is that the strain-specific effects of individual probiotic components could together exert a broader spectrum of activity. Probiotics can be given in both powder and liquid form and positively modulate the composition of broiler intestinal microflora via the stimulation of potentially beneficial bacterial populations and the reduction of pathogenic bacteria. The interaction between probiotics and micro biota added to diet influences the microbial population’s stability and the health of the host. The gut micro biota plays a crucial role in host metabolism and fundamentally influences physiology, health and well-being, functionality and performance.

Yeasts have been reported to act as supporting agents for lactic acid bacteria but also as having the potential to reduce avian bacterial in the gut micro biota of poultry. Inconsistency in results about the correlation between yeast and lactic acid bacteria as probiotics has been evident since the early publications on use in broilers. Accordingly, the current study aims to determine the relationship between lactic acid bacteria and yeasts as probiotics in broiler diets on growth performance, meat quality, blood parameters, and immune responses, through a meta-analysis using data from published articles.

Methods

Database development

A database was constructed based on peer-reviewed and published research articles which reported the use of probiotics in the broiler diet. Articles were selected based on the Systematic Review Center for Laboratory Animal Experimentation (SYRCLE’ method) and Preferred Reporting Items for Systematic Review and Meta-Analyses (PRISMA). Articles selected were taken from PubMed, Web of science, Scopus, Google Scholar, and Science direct databases as well as individual journals such as World Poultry Journal Science, British Poultry Science Journal, and International Journal of Poultry Science using the keywords ‘probiotic’, ‘broiler’, ‘performance’, ‘organ weight’, ‘carcass’, and ‘blood serum’. In each article evaluated, the reference list was also searched for relevant articles. The raw database information from articles, authors, year of study, broiler (strain and sex), diet used in trial, length of trial, level of treatment, form and dosage of probiotic contained in the study was recorded in a spreadsheet following the referenced method. After careful evaluation, the parameters included were growth performance, relative organ weight, carcass quality, blood parameters, and immune responses. While the economical parameters are not included due to insufficient data in the paper. The strains recorded on the raw database were Ross308, which dominated at 63.26%; Arbor Acres at 32.65%; and others at 4.09%.

Criteria for an article to be included in the database were as follows: (a) article was published in a peer-reviewed with range 2008–2020, this paper length was chosen as related to journals aged last 10–12 years are often good; (b) the broiler were modern-controlled-trial environment and management, (c) performed directly on broiler in vivo as the experimental animals, (d) The log concentration of lactic acid bacteria and yeast both powder and liquid form on the trial was transformation into 10^10 in the database development, (e) non-probiotic treatment excluded from the database, (e) the articles written consistently in English were considered in studies, (f) the average duration of the study was minimum 0–21 days and the maximum at 0–53 days, (g) dosages given at the range 0–10 g/kg from total feed formulation. Moreover, the dependent and independent variables were selected with the aim of lactic acid bacteria and yeast related as probiotic on the broiler. Likewise, data extraction was completed in accordance with the task analysis to obtain the exact values from graphical data, the relevant figure from the papers were subjected to an online tool, WebplotDigitizer 4.4 (https://automeris.io/WebPlotDigitizer/), following the method.
The final database consisted of 49 in vivo articles, 93 studies, and 225 n-total (3,375 n-total of total in this experiment). The details for the study selection included in this meta-analysis are provided in Figure 1. The search strategy is presented in Table 1. The summary of the final database is presented in Table 2, and PICOS criteria presented in Table 6.

Data analysis
Statistical dataset analysis using a mixed-model approach was applied\textsuperscript{11–14} with statement analysis in the system using the MIXED procedure of SAS (version 9.1, SAS Institute Inc., 2008), the following model was applied: The findings of a study was then taken as a random effect, while the supplementation concentration was taken as the fixed effect as follows\textsuperscript{15–17}:

\[
Y_{ij} = B_0 + B_1X_{ij} + B_2X_{ij}^2 + s_i + b_iX_{ij} + e_{ij}
\]

where \(Y_{ij}\) = the expected output for dependent variable \(Y\) at level \(j\) from the variable \(X\) as a continuous variable in the study \(i\), \(B_0\) = overall intercept across all studies (fixed effect), \(B_1\) = linear regression coefficient of \(Y\) on \(X\) (fixed effect), \(B_2\) = quadratic regression coefficient of \(Y\) on \(X\) (fixed effect), \(X_{ij}\) = value of the continuous predictor variable (probiotic supplementation level), \(s_i\) = random effect of study \(i\), \(b_i\) = random effect of study \(i\) on the regression coefficient of \(Y\) on \(X\) in study \(i\) and \(e_{ij}\) = unexplained residual error.

In the statement CLASS, the “study” variable was declared. Data were weighted by the number of replicates in each study. Additionally, an unstructured variance – covariance matrix (type = un) was performed at the random effect part of the model to avoid a positive correlation between intercepts and slopes. Significance of an effect was stated at the probability level of \(p < .05\), and \(p < .1\) was considered as a tendency of significance. In case that the quadratic model

above was not significant, the model was changed into its corresponding linear model. The variable of the study was declared in the class statement as it did not contain any quantitative information. The regression equations are also presented with \( p \)-value, and root mean square error (RMSE).
Furthermore, to determine (1) interaction between lactic acid bacteria and yeast; (2) interaction of type probiotic (powder and liquid) according to the following model\textsuperscript{16}:

\[ Y_{ij} = \mu + S_i + \tau_j + S\tau_{ij} + e_{ij} \]

Where \( Y_{ij} \) = the expected output for dependent variable \( Y \), \( \mu \) = overall mean, \( S_i \) = random effect of \( i \) study, \( \tau_j \) = fixed effect of the \( j \) level, \( S\tau_{ij} \) = random interaction between \( i \) study and the \( j \) level, and \( e_{ij} \) = residual error. A significant effect was declared at \( p<0.05 \) or there is a tendency when the \( p \)-value was between 0.05 and 0.10.

**Results**

Table 3 presents the effects of probiotics on broiler performance. The meta-analysis results show the level of probiotic (\( p<0.001 \)) body weight, body weight gain, and feed intake of broilers. In contrast, there was a reduction (\( p <0.01 \)) on feed conversion ratio (FCR) and mortality on the level probiotic given to broiler. Furthermore, the analysis also shows that the form of probiotic in the feed does not create any significant difference in broiler performance.

The weight of abdominal organs and carcass yield of broilers were affected by the supplementation of probiotics in the diet (Table 4). Supplementation of probiotics in broiler diet increased (\( p <0.001 \)) the weight of liver, spleen, gizzard, bursa of Fabricius and carcass yield, while reduced (\( p<0.001 \)) abdominal fat weight. Different types of probiotic, i.e., powder or liquid, influenced the weight of liver (\( p =0.001 \)), spleen (\( p <0.005 \)), gizzard (\( p =0.045 \)) and bursa of Fabricius, (\( p <0.001 \)). In contrast, abdominal fat and carcass yield were not affected by the type of probiotics supplemented in the diet. Further, different culture type, i.e., lactic acid bacteria or yeast, had no significant effect on the abdominal organs weight and carcass yield of broilers.

The effects on blood parameters of lactic acid bacteria and yeasts as probiotics are presented in Table 5. The probiotic given increased the total of red and white blood cells (both at

Discussion
The effect of probiotics on growth performance
Our meta-analysis shows that probiotics positively affect growth performance. In terms of growth performance, we suggest that this finding is related to the ability of probiotics to induce intestinal mechanisms, resulting in a reduction in pathogenic bacteria. In the digestive system, intestinal pH, intestinal bacteria composition, and digestive activity are improved when probiotics are present in diets. Some probiotics are known to produce enzymes, amylase, protease, and lipase to optimize nutrients’ breakdown. They can also increase specific enzymes in the host digestive tract to enhance nutrient absorption in the diet. In the poultry industry, probiotics are supplemented into the diet to maintain health by enhancing gut health, modulating the immune system, lowering glycaemic response, and improving various performances parameters. Moreover, the administering of probiotics has several ways in practice. The administering of probiotics can be included in the basal diet or combined with raw materials that contain prebiotics to enhance its effect. The probiotic can be given alone or with another additive without any negative effect such as acidifiers and phytogenics. Furthermore, probiotics can contain one or multiple microorganism strains that can be added to animals’ diets.

There are previous studies that report that cell-wall components of yeast in dietary supplementation to lactic acid bacteria improve the growth rate, feed consumption, and feed efficiency in broilers. These positive and consistent results were due to yeast activating spores to reduce and remove potential pathogens in the gut which possibly increases body weight. Linearly, the factors related to synergism between yeast and lactic acid bacteria reported in the research could be related to environmental conditions in various experiments.

One study from showed that rearing the broiler with a heat-stress environment at 35°C was more low weight than heat stress exposed. Thus, yeast failed to alleviate heat-stress on the performance of broiler. The lower temperature in the chicken house may help increase feed intake to eat more of the experimental diets. Another result explains in more detail that yeasts in powder form significantly increase the body weight of broilers starting at 21 days old, with an increase...
in line with increasing feed intake and reducing FCR. These consistent results explain that the use of lactic acid bacteria as probiotics in powder form help to increase the body weight of broilers, as a result of digestibility and metabolic process improvement caused by the bacteria, affecting energy partition and putting more energy into growth than maintenance.

Moreover, the positive use of probiotics both as powders and liquids was in line with the increasing level of treatment in broiler. The probiotics enhance liquid lactic acid bacteria synergism with yeast in the feed but suggested at an optimized level of 0.8%. However, the dose-response relationship of probiotics in animal trials is rarely studied. At low doses a probiotic may be specific, for example bifidobacteria, due to the high specificity of bifidobacteria for that particular probiotic. In other hand, if the dose increased, this would leave some substrate for other probiotic strains able to ferment it. The outcome of high dose would show less specificity that that of the low dose. Treatment with both powder and liquid forms increases body weight and feed intake and reduces feed conversion. Moreover, probiotics for farm animals have positive effects on growth, efficiency of feed utilization. Thus, utilization of feed is also reflected on the nutrient digestibility. In addition, the consistent result in studies vs 50–52 show the relationship between both yeast and lactic acid bacteria working together to reduce potential pathogens in the gut of broilers but dose is dependent.

The effect of probiotic on the relative organ weight and carcass quality

The meta-analysis results show limited effects on the carcass and organ weight of broilers. In agreement from 52,62 the carcass quality shows no significant difference after administering probiotics of both lactic acid bacteria and yeast. The one factor can be caused reduced of percentage carcass are heat-stress environmental. The carcass heat-stress was associated with the reduced of carcass quality. Apart from physiological adjustment derived from depressed feed intake, the increased Corticosterone level may be responsible lower percentage of carcass. Carcass percentage was reported to be increased by one study, with the saleable product in terms of edible portions. Reported the carcass quality can be affected from physiological and genetic potential, feed formulated, strain of the broiler rearing. The excess fat deposition in carcass of broiler is undesirable to producers because of reduced carcass yield and to consumers that prefer a leaner product.

Likewise, one study the use of yeast as probiotic reduced abdominal fat of broiler. Reported yeast help to reduce fat deposition because, modern-broiler-farming were intensive feeding (ad-libitum), fatter caused limb defects, and sudden death syndrome. The probiotics reported reduced fat of broiler compared without probiotic. The mode of action was that probiotics decreased the activity of acetyl-CoA carboxylase. Acetyl-CoA carboxylase has been widely suggested as the rate-limiting enzyme in fatty acid synthesis. The decline in the synthesis of fatty acids, in turn, would decrease their availability for esterification to triglycerides for deposed in the adipose tissue. Furthermore, the minimum dose of probiotic to stimulate fatty acids are currently unknown. Differences in the broiler line/breed and conditions, as well as microorganism strains (highly species-and strain specific), origin species, concentrations, and methods of administration of the probiotic bacteria, may explain these results. However, our study can’t exactly suggest the dose optimum for using this probiotic.

In one study, the effects of probiotics on relative weights of liver and spleen were not significant (P > 0.05), while bursa of Fabricius relative weight increased (p < 0.05). Supplemening diets with probiotics could help to prevent necrotic enteritis which associated with degeneration of hepatocytes and immune system of the broiler. The smaller liver in broiler may indicate a higher resistance to pathogen microorganism such as Clostridium perfringens. The IGF-1 can produce short-fatty acids (SCFAs), which act either directly or indirectly on the liver and adipose tissue to promote growth of organ and skeletal development. The report from 72 at the end of the feeding trial showed that the development of gizzard weight was decreased, dateable irregularities in the gizzard are a sensitive index to reduce anti-nutritional factors in the basal diet after exposure to toxic substance not to amount of lactic bacteria. Moreover, increased weight of this lymphoid organ may indicate a higher immunity achieved in treated broiler, which could be explained by probiotic anti-microbial activity. The factor affected by significant differences in the relative organ weight is the ability to absorb substances from probiotics. Stated that variances between the broilers result from impacts on absorption and other capacities of the relative organ weight. The growth factors correlate with age, while the broiler’s uses in the relative age cause the same internal organ’s growth. In instances, an increased relative organ weight may be in line with an increase in lymphocyte concentration.

The effect of probiotic on the blood parameters and immune responses

The meta-analysis of different probiotic levels on some blood parameters showed red and white blood cell concentration increased (p <0.05) with increasing probiotic supplementation levels in the feed. The increased of the white blood cells had correlated with yeast reduce the uric acid (UA) content in the blood. The uric acid is a metabolite of protein that has an antioxidant function, but is converted to a pro-oxidant in the cell or cytoplasm. In contrast, lymphocyte, and hemoglobin were not significantly different (p >0.05). Linearly, blood serum rose in line with probiotic increase. Additionally, one study shows that the lactic acid bacteria that help reduce avian-pathogenic bacteria were Escherichia coli and Clostridium perfringens. The beneficial action indicates that lactic acid bacteria produced extracellular enzymes to enhance the nutrient digestibility of feed and synthesize immune function using endogenous anti-microbial. In terms of negative linear response in studies there was no positive result on red and white blood cells.

Moreover, probiotics could be related to a lowered recycling of bile salts in the gut or inhibited hepatic 3-hydroxy-3-methylglutaryl coenzyme A reductase activity. The mechanism operating in lactic acid bacteria, as probiotics to elicit
their hypocholesterolemic effect is interference with intestinal bile acid transport and absorption, leading to an increase in bile acid excretion\(^{11}\). The potential pathogens reduce but are not eliminated, thus, probiotics balance the intestinal environment to enhance the broiler’s immune systems\(^{14,50–52}\). Although, the lactic acid bacteria do not produce butyric acid themselves, they stimulate the proliferation of butyric acid and cell-wall of yeast in the blood circulation by the mechanism that is called cross-feeding\(^{22}\). Continued research\(^{42}\) shows probiotics help to increase the white blood cell count as level of probiotic is increased. One study\(^{42}\) stated that the increase of white blood cells and immune response was due to the level increase of B and T lymphocyte production. In line with the 41 studies the amount of red blood cells, hemoglobin, and white blood cells consistently tends to increase compared to controls. The positive effect from yeast as a probiotic could derive from its outer cell wall components namely: chitin, mannan, and glucan which have an immunostimulant effect. Moreover, these outer wall components promote lactic acid bacteria activity, which is activated by producing enzymes that cause disintegration of bile salts, making them unconjugated\(^{48}\). The yeast can enhance the immune response by promoting growth of lactic acid bacteria and thus simultaneously producing antibacterial substances and stimulating the production of immunoglobulin\(^{11}\). Thus, yeast acts as a supporting agent of lactic acid bacteria, which adhere to the endogenous epithelial cells to initiate colonization\(^{17}\).

Conclusions

The results provided by this meta-analysis demonstrates the enhancement of overall performance of broilers supplemented with lactic acid bacteria and yeast as probiotics. Effects of the probiotics on blood parameters are dose dependent, where the ads, the additives have limited effects on organ weight and carcass percentage. Both powder and liquid forms of probiotics do not affect the results differently. The future research trends are to determine the dose optimum of probiotic for broiler.

Data availability

Underlying data

All data underlying the results are available as part of the article and no additional source data are required.

Extended data

Figshare: Extended data for ‘The effects of lactic acid bacteria and yeasts as probiotics on the growth performance, relative organ weight, blood parameters, and immune responses of broiler: A meta-analysis’. https://doi.org/10.6084/m9.figshare.1406041\(^{24}\).

This project contains extracted data of outcome measures (BW: body weight; BWG: body weight gain; FCR: feed conversion ratio; FI; feed intake; RBC: red blood cell; WBC: white blood cell).

This MS has an updated review on the use of lactic acid bacteria and yeasts as probiotics on the growth performance, relative organ weight, blood parameters, and immune responses of broiler: A meta-analysis of value to broilers industry. The MS has provided helpful information about the concept of probiotics and their role in enhancing performance, health and product quality.

Major concern

- To go one step further, the dose of lactic acid bacteria and yeasts should be estimated based on this work.

- The update and renewable application of lactic acid bacteria and yeasts in broilers should given considered attention such as: compact of heat stress; control of infectious diseases; and detoxification of nitrate and aflatoxin. I have included some of my works which are good examples:

  - Control of Salmonella enteritidis infection in male layer chickens by acetic acid and/or prebiotics, probiotics, and antibiotics¹.

  - The detoxication of nitrate by two antioxidants or a probiotic, and the effects on blood and seminal plasma profiles and reproductive function of New Zealand White rabbit bucks².

  - Enhancing Tolerance of Broiler Chickens to Heat Stress by Supplementation with Vitamin E, Vitamin C and/or Probiotics³.

  - Nitrate detoxification using antioxidants and probiotics in the water for rabbits⁴.

  - Health Benefits of Probiotics in Human and Animal Nutrition and Prospective Research.
Effects of different dietary levels of blue lupine (Lupinus angustifolius) seed meal with or without probiotics on the performance, carcass criteria, immune organs, and gut morphology of broiler chickens.  

Minor concern
- Improve the language as the MS needs an English language and grammar edit.
- Enhancing the MS with figures and infographics can improve readability of the MS.

References

Are the rationale for, and objectives of, the Systematic Review clearly stated?
Yes

Are sufficient details of the methods and analysis provided to allow replication by others?
Yes

Is the statistical analysis and its interpretation appropriate?
Yes

Are the conclusions drawn adequately supported by the results presented in the review?
Partly

*Competing Interests:* No competing interests were disclosed.

*Reviewer Expertise:* Poultry production and nutrition

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.

Please specify what is the object of this study.

You could add an Economic interpretation of this study.

Data in the Results section were insufficient and need more clear for discussion.

This paragraph is not understandable:

“Criteria for an article to be included in database were as follows: (a) article was published in a peer-reviewed with range 2008–2020, this paper length was chosen as related to journals aged last 10–12 years are often good9 (b) the broiler were modern-controlled-trial environment and management, (c) performed directly on broiler in vivo as the experimental animals, (d) The log concentration of lactic acid bacteria and yeast both powder and liquid form on the trial was transformation into 1010 in the database development, (e) non-probiotic treatment excluded from the database, (f) the articles written consistently in English were considered in studies, (f) the average duration of the study was minimum 0–21 days and the maximum from total feed formulation. Moreover, the dependent and independent variables were selected with the aim of lactic acid bacteria and yeast related as probiotic on the broiler. Likewise, data extraction was completed in accordance with the task analysis to obtain the exact values from graphical data, the relevant figure from the papers were subjected to an online tool, WebplotDigitizer 4.4 (https://automeris.io/WebPlotDigitizer/), following the method10".

I suggest an English language edit for the revision of the manuscript.

**Are the rationale for, and objectives of, the Systematic Review clearly stated?**
Partly

**Are sufficient details of the methods and analysis provided to allow replication by others?**
Partly

**Is the statistical analysis and its interpretation appropriate?**
Partly

**Are the conclusions drawn adequately supported by the results presented in the review?**
Yes

**Competing Interests:** No competing interests were disclosed.

**Reviewer Expertise:** Veterinary Pharmacology.

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.
Danung Nur Adli, University of Brawijaya, Malang, Indonesia

We would like to express our sincere thanks and appreciation for comprehensively reviewed our manuscript that helped us to improve our manuscript. Regarding the reviewer suggestion and question

1. Please specify what is the object of this study.
   **Answer:** We already mentioned in the introduction that "Accordingly, the current study aims to determine the relationship between lactic acid bacteria and yeasts as probiotics in broiler diets on growth performance, meat quality, blood parameters, and immune responses, through a meta-analysis using data from published articles".

2. You could add an Economic interpretation of this study.
   **Answer:** Thank you for the suggestion. Regarding this suggestion the economic parameters, initially we input this parameter but in final paper we don't put down this parameter due to lack of data provided in the paper.

3. Data in the Results section were insufficient and need more clear for discussion.
   **Answer:** We mentioned clearly in the result section.

4. **Answer:** The statement that you are asking for are the requirements when we select the paper and criteria when we put down the information, to develop the data.

5. I suggest an English language edit for the revision of the manuscript.
   **Answer:** Authors would like say thank to second reviewer. The manuscript has been edited for English language usage by a native British proof-reader of Britannia Proofreading Service.

**Competing Interests:** No competing interests were disclosed.
The benefits of publishing with F1000Research:

- Your article is published within days, with no editorial bias
- You can publish traditional articles, null/negative results, case reports, data notes and more
- The peer review process is transparent and collaborative
- Your article is indexed in PubMed after passing peer review
- Dedicated customer support at every stage

For pre-submission enquiries, contact research@f1000.com
