Abstract

Introduction: Acne is a chronic inflammatory disorder of the pilosebaceous unit with differential pathogenesis. To elucidate the roles of hormones in acne pathogenesis, we conducted a study to evaluate the serum testosterone, estradiol, progesterone levels in women with acne vulgaris.

Methods: We conducted a cross-sectional descriptive study, and 175 women with acne vulgaris were examined; their serum estradiol, progesterone, testosterone were analyzed by chemiluminescence technique and compared with the healthy control group.

Results: Increased serum hormone levels in women with acne vulgaris were accounted for 29.7%, and hyperandrogenism was accounted for 16.0% of cases. We found significant differences in testosterone levels (mean value, 55.67±25.56 versus 38.37±10.16 ng/dL, p<0.05) respectively in the acne group and the control group. However, the estradiol level of the acne group (323.15±93.31 pmol/L) was lower than the control group (370.94±58.88 pmol/L) with p<0.05). No statistically significant differences were found for progesterone (0.60±0.38 versus 0.50±0.15 ng/mL, p>0.05) levels. Moreover, we did not find the relationship between serum hormone levels and the severity of acne vulgaris.

Conclusion: This study showed that the female acne vulgaris patients may have high serum testosterone levels and low serum estradiol levels compared with those of female controls. However, hormone alterations had no correlation with the acne grades.

Acne vulgaris, hormone
Introduction
Acne is a chronic inflammatory disorder of the pilosebaceous unit with various manifestations, including non-inflammatory and inflammation lesions. Collier et al. (2008) investigated 1013 Americans aged 20 years and older; 73.3% (744) reported ever having acne, more women suffer from acne than men. Four major factors involved in acne pathogenesis are excessive sebum production, follicular hyperkeratinization, hyper-colonization of the duct by *Cutibacterium acnes* (formerly *Propionibacterium acnes*), and the production of inflammation. Moreover, the hormone plays a crucial role in the pathogenesis of acne. Some studies found that acne had a relationship with hyperandrogenemia in female patients. Estradiol, the primary female sex hormone is known as the major active estrogen, forms in absolute serum levels and estrogenic activity during human female reproductive years. Supplying sufficient amounts of estrogens will decrease sebum production and may act by suppressing androgen production by inhibiting the pituitary from secreting gonadotropin. The effect of progesterone on sebaceous glands was still disputed. Some authors have blamed progesterone for the change of sebum production in females during the menstrual cycle. However, this theory has not been proved experimentally. Therefore, we conducted this study to evaluate the serum testosterone, estradiol, and progesterone levels and the correlation of hormonal alterations with the severity of acne in women with acne vulgaris.

Methods
Study design
A cross-sectional study was conducted from January to October 2019 to concentrate serum estradiol, progesterone, testosterone levels in female acne patients at the Dermatology department of 103 military hospital, Vietnam.

Inclusion criteria
The inclusion criteria for acne patients were females aged 16 to 30 years and diagnosed with acne vulgaris.

The control group’s criteria were healthy females without pregnancy or lactation.

Exclusion criteria
Exclusion criteria were: diagnosis with (1) other types of acne; (2) patients with polycystic ovary syndrome; (3) using hormone contraceptives or other hormones; (4) a history of ovarian or pelvic surgery; (5) pregnant or breastfeeding women.

Methodology
This was a prospective, cross-sectional descriptive study with control samples.

The sample size was based on the below formula and the research result of da Cunha (2013), we got \( n = 148 \).

\[
n = \frac{Z_{1-\alpha/2}^2 \cdot (1 - p)p}{d^2}
\]

Techniques of the research
All patients for each group were asked about risk factors, clinically examined, were performed tests (control group, acne group), and registered to study records.

The acne grading score, according to Karen McKoy (2008), is as follows:

- Mild: less than 20 noninflammatory lesions or less than 15 inflammatory lesions or less than 30 total kinds of lesions.
- Moderate: 20–100 noninflammatory lesions or 15–50 inflammatory lesions or 30–125 total kinds of lesions.
- Severe: more than 05 papules/cysts or more than 100 noninflammatory lesions/more than 50 inflammatory lesions or more than 125 total kinds of lesions.

Assessment technique of plasma hormone levels: 4 mL of venous blood was collected at 08:00 h and during the follicular phase of the menstrual cycle (2nd to 4th day of menses). Blood samples are contained in a tube with EDTA anticoagulant solution. After being incubated at room temperature for 10–20 minutes, samples are centrifuged for about 20 minutes at 2000–3000 rpm. After centrifuging, taking the plasma part for testing, we used direct chemiluminescent technology for measuring hormone levels in the Unicel® DXI800 machine. Units: testosterone for ng/dL, estradiol for pmol/L, progesterone for ng/mL.
Data analysis
The data were analyzed by SPSS software version 22.0. Mean SD are in the form: $X \pm SD$, comparing two means using the student t-test. The research results were compared by the Chi-squared test, and a p-value <0.05 was considered to be of statistical significance.

Results
210 female participants were enrolled in the study and divided into 175 female patients with acne vulgaris and 35 healthy controls.

The mean age of patients and BMI showed no statistically significant difference between the study group and the control group with p>0.05 (Table 1).

The plasma testosterone level of the acne vulgaris patients was higher than the control group, respectively 55.67±25.56 ng/dL, 38.37±10.16 ng/dL. The difference was statistically significant with p<0.05. On the other hand, plasma estradiol level in acne vulgaris patients was lower than the control group with a statistically significant difference (p <0.05), respectively 323.15±93.31 pmol/L and 370.94±58.88 pmol/L. However, plasma progesterone levels were not different between both groups (Table 2).

52 patients (29.7%) out of 175 acne patients had hormonal alterations, including 28 patients (16%) with hyperandrogenism; 20 patients (11.43%) had increased serum progesterone level, only four patients (2.29%) had increased serum estradiol level, no patient had low hormonal levels (Table 3).

There were no different hormone levels between the grades of the acne vulgaris group and there were no different testosterone levels between the mild acne and control groups with p>0.05. However, testosterone levels in moderate and severe groups were statistically significantly higher than in the control group (p<0.05). Estradiol levels in the moderate and severe groups were statistically significantly lower than the control group with p<0.05. However, the estradiol level in the mild group was not significantly lower when compared with the control group. Progesterone levels in the mild and moderate groups were similar to the control group, except the severe group was higher than the control group; the difference was statistically significant with p<0.05 (Table 4).

Discussion
The gonads and the adrenal gland produce the majority of circulating androgens. However, androgens can also be produced locally within the sebaceous gland from the adrenal precursor hormone DHEAS (dehydroepiandrosterone sulfate). The major androgens interacting with the androgen receptor are testosterone and DHT (dihydrotestosterone). In addition, androgen receptors have been localized to the basal layer of the sebaceous gland and the outer root sheath keratinocytes.7

In 2013, da Cunha et al. investigated androgen levels in 835 female patients with acne vulgaris and found that the rate of androgenism was 10.77%.5 In 2014, Wei et al. studied endocrine disorders in 242 acne patients. The authors showed that serum testosterone levels were significantly increased in the acne patient group compared with controls.8 In this study, we found that the testosterone level of the acne group was higher than controls and the hyperandrogenism rate was 16%.

We hypothesize that estrogens might impact sebum secretion by three different mechanisms: the opposition of androgens within the sebaceous glands, inhibition of gonadal androgen production via a negative feedback mechanism on gonadotropin release, and has an effect on genes which play a role in sebaceous gland growth and lipid production.9 In 2014, Wei et al. surveyed 118 female acne patients compared with 90 sex-matched controls. The results showed that the estradiol level in the acne group decreased significantly compared with the control group with a p-value less than 0.001, respectively 263.81/14.83 pmol/L; 398.71/26.24 pmol/L.8 This result was also consistent with our result.

Testosterone is converted into a more potent form DHT by 5-ARD (5α-reductase) enzyme causing an excess sebum production, whereas progesterone inhibits the activity of this enzyme and prevents turning testosterone into DHT. So, progesterone itself might be expected to reduce sebaceous gland activity. However, the progesterone effect on acne remains unclear. Although some studies show that progesterone can reduce androgen effects by inhibiting the 5-ARD enzyme or androgen receptors,10 the fluctuation of sebum production in women during the menstrual cycle and premenstrual cyclic flare has partly been associated with progesterone, and some progestins lead to an exacerbation of acne by interacting with androgen receptors.10,11 In our study, there was no statically significant difference between the acne group and controls in terms of serum progesterone levels. However, the progesterone level of the severe acne was higher than the control group; the difference was statically significant with p<0.05.

Conclusion
This study showed that the female acne vulgaris patients might have high serum testosterone levels and low serum estradiol levels compared with those of female controls. However, hormone levels differences had no correlation with acne grade.

This manuscript evaluates serum hormone levels in women, comparing with a control group. The manuscript evaluated 3 hormones at menstruation period. However, the manuscript needs revision as:

Progesterone 0,5 vs 0,6 may be better analysed by increasing control size, which is too small (175 vs 35). Additionally severe acne vs control group progesterone levels are significantly different. For a better statistical analysis the control group should be nearly half, and I think, therefore, that increasing control size will be meaningful statistically. The same is applicable to progesterone levels.

Acne vulgaris is a term up to age 25, what is the rationale that you choose 30 years? Acne adultorum is supposed to be related to hormonal disturbances. Many acne adultorum patients are stressful working women, there is an increased rate of stress hormones such as prolactin and cortisol. It is better you exclude women over 25.

Estradiol, progesterone and testosterone levels are in fact not enough for hormonal evaluation in women.

Is the work clearly and accurately presented and does it cite the current literature?  
Yes

Is the study design appropriate and is the work technically sound?  
No

Are sufficient details of methods and analysis provided to allow replication by others?  
Yes

If applicable, is the statistical analysis and its interpretation appropriate?
Partly

**Are all the source data underlying the results available to ensure full reproducibility?**
No source data required

**Are the conclusions drawn adequately supported by the results?**
No

**Competing Interests:** No competing interests were disclosed.

**Reviewer Expertise:** Acne

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.

NGUYEN CUONG, Vietnam Military Medical University, HaNoi, Vietnam

1. Progesterone 0,5 vs 0,6 may be better analysed by increasing control size, which is too small (175 vs 35). Additionally severe acne vs control group progesterone levels are significantly different. For a better statistical analysis the control group should be nearly half, and I think, therefore, that increasing control size will be meaningful statistically. The same is applicable to progesterone levels.

- This article studied the relationship between acne vulgaris with three degrees of disease and hormone levels. And mild acne was found not in relation to sex hormone disorders. This study tried to find this relationship in the moderate and severe groups, with 35 patients in each group. So we decided to choose the control group of around 35 patients. To be more meaningful statistically, we will increase the number of patients in the control group.

2. Acne vulgaris is a term up to age 25, what is the rationale that you choose 30 years? Acne adultorum is supposed to be related to hormonal disturbances. Many acne adultorum patients are stressful working women, there is an increased rate of stress hormones such as prolactin and cortisol. It is better you exclude women over 25.

Acne that occurs in patients over 25 years old is called post-adolescent acne, and the hormone levels in these patients will be affected by external factors such as stress. And our study first chooses female acne patients ranging from 16 to 30. When we checked our data and found that patients over 25 years old had no change in my statistical data, we could replace the inclusive criteria field that we chose the patients from 16 to 25 years old.

3. Estradiol, progesterone, and testosterone levels are in fact not enough for hormonal evaluation in women.

- Thank you for your comment. We will consider changing the article to “Assessment of serum testosterone, estradiol, and progesterone levels in female patients with acne”.
