Abstract
Satisfactory pain treatment could prevent adverse physical and psychological outcomes in patients. In this sense, adequate survey to measure patient satisfaction of pain management is important. In this study, we translated the Pain Treatment Satisfaction Scale to Spanish and analyzed the psychometric properties of its five dimensions. Reliability was determined with Cronbach’s-α and convergent and divergent validity with a multitrait-multimethod analysis. The latter were reported as successful percentage. In the five dimensions, the reliability of the Spanish version showed Cronbach’s-α values ≥ 0.75; successful percentage for convergent validity was ≥ 88, and successful percentage for divergent validity was ≥ 94. The Spanish version showed good psychometric properties and can be used to measure pain treatment satisfaction.

**Introduction**

Satisfactory pain management is important to prevent adverse physical and psychological results for patients and their families. Through the activation of the pituitary-adrenal axis, inadequate pain treatment could produce postsurgical infection and poor wound healing. Pain also activates the sympathetic nervous system, which results in disruption of the cardiovascular, gastrointestinal and renal systems. In addition, patients with pain may have a sense of helplessness or hopelessness. This may predispose them to anxiety and depression, and they may be reluctant to seek medical care for other health problems.

Adequate pain control can improve the patient’s attitudes and behaviors toward their treatment. They are more willing to comply with the advice of their health care provider, miss fewer medical appointments and are more likely to adhere to their medical treatment. In this sense, surveys to measure patient satisfaction and pain treatment are important for adequate health care. The aim of this study was to translate the Pain Treatment Satisfaction Scale (PTSS) into Spanish and analyze some of its psychometric properties.

**Methods**

**Survey.** The PTSS was developed by Evans et al. and validated to assess satisfaction in patients with both acute and chronic pain. This survey includes 39 items grouped into five dimensions: information about your pain and treatment (5 items); medical care (8 items); impact of current pain medication (8 items); satisfaction with pain medication, which included the two subscales medication characteristics (3 items) and efficacy (3 items); and side effects (12 items). Each item is measured with a 5 point-Likert scale which ranges from 1 (major satisfaction) to 5 (worst satisfaction). Scales and items were transformed to a 0 to 100 score, where 100 represents highest satisfaction.

**Translation.** This process was carried out in 4 steps. In the first step, 2 authors, experts in pain medicine (TANO and SCG), performed the translation from English to Spanish. In the second step, all authors reviewed the translation and gave suggestions and recommendations to improve the clarity of the items. In the third step, external professional translators made the inverse translation from Spanish to English. In the final step, all authors reviewed both the inverse translation and the original survey.

**Sample.** We applied the Spanish version to a random sample of 174 patients from the Dr Jose E. Gonzalez University Hospital with some type of pain. They were interviewed in the postoperative or ambulatory areas. Patients older than 18 years who gave verbal consent were included in this study. The Ethical Committee of the Faculty of Medicine of the Autonomous University of Nuevo León approved this study, and exempted from written informed consent. The reference number is AN15-004.

**Statistical analysis.** Results of each dimension were calculate. Reliability was measured with Chronbach’s alpha test. The criterion of acceptability was 0.7. The construct validity, which included convergent and divergent validity, was evaluated with a multitrait-multimethod analysis. Convergent validity and divergent validity were expressed as %successful. Convergent validity was calculated with the following formula %successful = [(correlations “item–dimension to which it belongs >0.4”)/(total correlations “item–dimension to which it belongs”)]*100. The formula for divergent validity was %successful = [(number of correlations item – dimension lesser that correlations item-dimension to which it belongs)/(total correlations item-dimension to which it does not belong)]*100. Correlations were obtained with the matrix multitrait-multimethod. The statistical software SPSS 21 and the package Psy for R 3.2.2 were used for the analyses.

**Results**

**Table 1. Mean PTSS scores of pilot sample according to pain severity in the last week and last 24 hours.**

<table>

VAS scale for pain mild = 1 – 3; moderate = 4 – 7; intense = 8 – 10
Reliability and construct validity. The range of Chronbach’s alpha was 0.75 to 0.90, with medical care being the dimension with the lowest score and “impact of current pain medication” the dimension with the highest score. The %successful in convergent and divergent validity ranged from 88 to 100% and from 94 to 100%, respectively. “Medical care” (88%) and “side effects” (92%) were the dimensions with the lowest %successful in convergent validity, while medical care (94%) was the dimension with the lowest %successful in discriminant validity.

Discussion
In this study, we translated and preliminarily evaluated the psychometric properties of PTSS in its Spanish version. In other studies, this survey has been translated and validated in Chinese and French where good psychometric properties have been shown.

In the case of reliability, values obtained are satisfactory since values of all dimensions were > 0.70 and similar to the original version. In general, the values of all dimensions were slightly lower than the original version.

With respect to convergent and discriminant validity, results are satisfactory and similar to the original version. The medical care dimension had lower values than the original in both convergent and discriminant validity. Side effects had a value slightly higher than the original. The rest of the dimensions had the same values as those of the original version.

The limitations of this study include lack of a rigorous diagnosis of the type of pain. The sample size was smaller than that used in other studies and finally, a test-retest analysis was not performed.

Conclusion
The Spanish version of PTSS has satisfactory psychometric properties and some of these are similar to the original version; therefore it could be considered a valid instrument to measure pain treatment satisfaction in a Mexican population.

Data availability

Author contributions
TANO and SCG conceived the study, DAFE an NGLC carried out the research, OGS and DPR prepared the first draft of the manuscript and performed the statistical analysis. All authors were involved in the revision of the draft manuscript and have agreed to the final content.

Competing interests
No competing interests were disclosed.

I've looked at the paper and generally it reads well, and doesn't seem to have many major problems methodologically, other than the fact that normally, for convergent and divergent validity, different scales that measure similar and dissimilar dimensions are used.

What the authors refer to as divergent and convergent validity in their manuscript when they compare the Spanish and English versions. This is simply the concordance between the scores of English and Spanish instruments, which gives between 88%-100% concordance. This simply might reflect language proficiency effects. I would suggest, therefore that the authors choose some other term for this than convergent and divergent validity as this is incorrect.

I have read this submission. I believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.

The paper "Spanish translation and preliminary validation of the Pain Treatment Satisfaction Scale" evaluates the validity of an already published pain treatment satisfaction scale, presented in a Spanish translation, on a Mexican population. After a careful double checked translation, the paper concludes that it is adequate for use in the pre-defined population.

This paper is published as a Research note, and indeed, considering the number of items included in the score (39), it can hardly be proposed in clinical practice for repeated measures.

If the quality of the translation has obviously been well controlled, it is not the case for the study population. No estimation of the number of subjects required to demonstrate the validity of the score has
been made, despite the fact that the authors had comparators against which they could perform this estimation. 174 appears as a very low number for a population including both acute and chronic pain in a vast variety of patients. Indeed, if the translation is accurate, any difference in its validity will come mainly from socio-cultural factors in the population. The authors themselves are indeed conscious of this limitation, but they could have easily corrected it.
